Highway Safety Literature

U.S. Department of Transportation **National Highway Traffic Safety Administration**

TD 8.10:

NOTICE

Highway Safety Literature is a monthly publication of the National Highway Traffic Safety Administration (NHTSA). It is divided into the following sections: Abstract Citations, containing bibliographical information and abstracts; and an Index to Abstracts, including a keyword-out-of-context (KWOC) list of words in the title, followed by the full title and HS number (our accession number); an Author Index; a Corporate Author Index; a Contract Number Index; and a Report Number Index. In those months when information on contracts recently awarded is available, a section entitled Contracts Awarded is added at the back.

Abstracts appearing in **Highway Safety Literature** represent documents acquired by the Technical Reference Branch, NHTSA. Documents related to the mission of NHTSA may be sent to the Editor at the address below for inclusion in the collection and abstracting in this publication. Please indicate availability source and price for each document.

Note: Publication of articles or abstracts in Highway Safety Literature is intended only for information. Views expressed are those of the authors and not necessarily those of the Administration. Reference to brand names, equipment, models or companies does not imply endorsement by NHTSA or the U.S. Department of Transportation.

Comments on the articles appearing in **Highway Safety Literature** may be addressed to

Editor
Highway Safety Literature
Technical Reference Branch
National Highway Traffic Safety Administration
400 7th St. SW
Washington, D.C. 20590

AVAILABILITY OF DOCUMENTS

Documents listed in *Highway Safety Literature* are not available from the National Highway Traffic Safety Administration unless so specified. They must be ordered from the sources indicated on the citations, usually at cost. Ordering information for the most common sources is given below.

NTIS: National Technical Information Service, Springfield, Va. 22161. **Order by title and accession number: PB, AD, or HS.** When no PB number is given for NHTSA Technical Reports, order by prefacing the HS number with DOT, i.e. DOT-HS-000 000.

GPO: Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. **Give corporate author, title, personal author, and catalog or stock number.**

Reference copy only: Documents may be examined at the NHTSA Technical Reference Branch or borrowed on inter-library loan through your local library.

See publication: Articles in journals, papers in proceedings, or chapters in books are found in the publication cited. These publications may be in libraries or purchased from publishers or dealers.

SAE: Society of Automotive Engineers, Dept. HSL, 400 Commonwealth Drive, Warrendale, Pa. 15096. Order by title and SAE report number.

TRB: Transportation Research Board, National Academy of Sciences, 2101 Constitution Ave., N.W., Washington, D.C. 20418.

Corporate author: Inquiries should be addressed to the organization listed in the individual citation.

ABSTRACT CITATIONS

SAMPLE ENTRIES

FORMAT OF ENTRIES IN HIGHWAY SAFETY LITERATURE

NHTSA accession number	HS-013 124
Title of document	**MAXIMUM BRAKE PEDAL FORCES PRODUCED BY MALE AND FEMALE DRIVERS**
Abstract	The object of this research was to obtain data concerning the maximum amount of brake pedal force that automobile drivers were able to sustain over a period of ten seconds. Subjects were told to apply the brakes in the test car as they would in a panic stop, and to exert as much force as possible on the pedal over the entire ten second test period. A total of 84 subjects were tested, including 42 males and 42 females. The results indicated that there is a wide distribution of values which characterizes the pedal force that the subjects were able to generate. Male subjects produced generally higher forces than did females. Over half the women tested were unable to exert more than 150 lbs. of force with either foot alone, but when both feet were applied to the pedal, force levels rose significantly.

NHTSA accession number	HS-018 924
Title of document	**NATURAL FREQUENCIES OF THE BIAS TIRE**
Abstract	The lowest natural frequencies of a bias tire under inflation pressure are deduced by assuming the bias tire as a composite structure of a bias-laminated, toroidal membrane shell and rigorously taking three displacement components into consideration. The point collocation method is used to solve a derived system of differential equations with variable coefficients. It is found that the lowest natural frequencies calculated for two kinds of bias tire agree well with the corresponding experimental results in a wide range of inflation pressures. Results of the approximate analysis show that the influences of the in-plane inertia forces on natural frequency may be considered small, but the influences of in-plane displacements are large, particularly on the natural frequency of the tire under low inflation pressure.

THE NIGHTTIME LEGIBILITY OF HIGHWAY SIGNS AS A FUNCTION OF THEIR LUMINANCE CHARACTERISTICS

A laboratory study was carried out to define the effects of luminance, contrast, color, and driver visual characteristics on sign legibility distance. At the same time a computer model was developed which predicts the legibility distance of a sign, based on laboratory data as well as geometric and photometric variables. A field study was then conducted in which legibility distance predicted by the model was compared with legibility distance measured on a number of real and simulated traffic signs, using a sample of normal drivers. In general, the predictions were within 10% of the measured legibility distances. The results indicate that more highly reflective backgrounds permit somewhat greater legibility distances and reduce the effect of changes in viewing conditions, which can be quite substantial for nonreflective backgrounds. The contrast provided by the legend is very important. Luminance contrast requirements are lowest for highly reflective backgrounds and increase as background reflectivity decreases. In this study, the luminance variables have been expressed in terms of material options available to the traffic engineer. If the data are accurate, as they appear to be, this form of presentation enables material choices to be made at a desk, without instrumentation of any kind. Some related problem areas which require study are the effect of glare sources near the sign, and the maximum acceptable background luminance level.

RAPID COMPREHENSION OF VERBAL AND SYMBOLIC TRAFFIC SIGN MESSAGES

A "same"/"different" reaction time procedure was used in two experiments to measures the times required to comprehend the meanings of projected slides of traffic signs. The results indicate that signs with symbolic messages can be understood more quickly than those with verbal messages. Visually degrading the signs resulted in a greater decrement in performance for verbal than for symbolic signs. correlational analyses demonstrated reaction time to correlate significantly with a previously obtained measure of sign legibility taken from a moving motor vehicle on a roadway. It is suggested that when ever a traffic sign is to be placed at a particular location, the version should be chosen which displays the intended message the most effectively under the expected environmental conditions. If the relative adequacy of the available versions were unknown, it could be assesed by the techniques of the present study; if no testing were to be done, a symbolic sign should be installed. It is recommended that both legibility distance and reaction time measures be taken whenever a complete evaluation of sign adequacy is undertaken. As a cost- and time-saving measure, a laboratory measure of legibility distance is currently under development.

RAILROAD CROSSING SAFETY

Although Amtrak statistics show that no school buses were involved in grade crossing accidents with Amtrak trains during the years 1975 through 1977, and the Dept. of Transportation states that school bus transportation is seven times safer than passenger car transportation in terms of injuries/passenger mile, the railroad train still poses a hazard to school buses. As a reminder to school bus drivers, the procedure for crossing railroad tracks, from the U.S. Instruction Manual, is presented. These guidelines include requesting silence from passengers when prepared to stop; shifting into neutral after the bus is stopped, with bumper clear of tracks and with a clear view of tracks; opening driver's window and service door; shifting into starting gear after it has been determined no train is approaching; looking and listening a second time, then closing door and proceeding quickly and smooothly, without shifting gears; holding the bus in position, with use of parking brake depending on waiting time, if a train is approaching; keeping bus stationary at multi-track crossing until the second track is entirely visible; proceeding if safe crossing is ensured in the case of a stopped train of malfunctioning signal; proceeding around malfunctioning crossing gate only at direction of police or railroad authority; and making a safety stop and following directions of a flagman in control of crossing. The manual emphasizes that no student loading stops should occur within 300 or 400 yd of either side of railroad tracks.

TRANSPORT STATISTICS GREAT BRITAIN 1967-1977

A comprehensive range of statistical information is tabulated on inland surface transport in Great Britain covering the period 1967-1977; some data span shorter or longer periods, and some are forecasts. to provide a wider setting for the inland surface transport statistical information, some summary tables on air and sea transport are included as are key transport figures relating to other countries. Metric units are generally used; a notes/definitions section gives detailed explanatory notes appropriate to the tables; a subject index is provided. Tables and maps are presented in the following parts (and sections): general (expenditure, travel, long-distance travel, freight transport); road expenditure and network; road traffic; motor vehicle stock and new registrations; car ownership; public road passenger transport; road goods transport; driving licenses and tests; vehicle tests; railways; accidents; inland waterways; sea transport; air transport; oil and petroleum pipelines; international; and miscellaneous (energy; forecasts of national road traffic, total inland freight, and passenger transport; pollution; employment; overseas travel and tourism; motor vehicle offenses).

THE SPECTRUM OF SEAT BELT INJURIES

A review is presented of seat belt injury types, the degree of severity ranging from minor contusions and lacerations to rupture and transection of vital structure. Intra-abdominal, genitourinary tract, thoracic, musculoskeletal, and miscellaneous (very uncommon injuries such as those to a major blood vessel) injuries are described; diagrams and texts point out lower trunk (lateral and posterior anterior views) symptoms and possible causes, and abdominal organs and possible injuries. Case histories are presented for two young men who were belted rear-seat occupants at the time their vehicle struck a pillar supporting an elevated railroad. Both men sustained abdominal injuries requiring surgery. A concluding remark advocates the use of restraint systems by all car occupants and calls for the development of better safety systems in the future. Editor's supplementary comments deal with proper adjustment of seat belts (with specific mention of quick-release buckles that pop open under certain conditions). Federal Motor Vehicle Safety Standards for restraint systems, and a physician's comment on the injury potential of restraints.

SILICONE BRAKE FLUID: ANSWER TO CORROSION

Silicone-based brake fluids meet brake engineers' requirements (stability for the life of the vehicle, noncorrosivity, a high boiling point unaffected by atmospheric conditions, and the lowest possible viscosity at -40 degree F) and offer the promise of eliminating replacement of hydraulic components for the life of the vehicle. The slight shrinkage of brake system seals associated with unformulated silicone fluids has been overcome through the addition of additives in small amounts. The automotive industry has been justifiably cautious in their approach to silicone-based brake fluids, as current fluids have served adequately. For fleet owners, doubling or tripling the life of wheel or master brake cylinders could result in significant savings. The U.S. Army, Dept. of Transportation, and silicone manufacturers have long been involved in the continual improvement and exhaustive testing of silicone-based formulations. Dow Corning Corp. has tested these brake fluids for over seven years in nearly 200 vehicles (with total mileage approaching 3 million). Testing by the Army of 1/4-ton vehicles for one year in Alaska and two years in Arizona and the Panama Canal Zone showed better performance of silicone vs. conventional brake fluids in terms of corrosion and gumming. As a result of these tests, the Army has issued MIL-*B-46176 covering silicone brake fluids, and is preparing for an across-the-board conversion. The U.S. Postal Service is well on its way to complete conversion. Several private fleet owners are actively testing silicone brake fluids. A General Services Administration decision to convert is contingent upon having the brake fluid available as an option from at least two vehicle manufacturers. The National Hwy. Traffic Safety Administration is funding a feasibility study for a long-life braking system regulation.

TINTED WINDSHIELD INVOLVEMENT AMONG CPIR [COLLISION PERFORMANCE AND INJURY REPORT] ACCIDENTS. FINAL REPORT

The 9222 vehicles in the CPIR3 (Collision Performance and injury Report) data set were examined for evidence that would indicate whether tinted windshields cause or prevent accidents. Windshield tint condition was known for 4185 vehicles, showing an almost even split between clear and tinted windshields. Vehicles with tinted windshields were found to be significantly underrepresented in the accident data compared to U.S. production figures (1971-1977 model years). Weighted least-squares regressions showed that the proportion of drivers having vehicles with tinted windshields increases as driver age increases, but that there are no statistically significant differences between daytime and nighttime conditions. The regression analyses results do not support the hypothesis that older drivers are negatively influenced by tinted windshields during nighttime driving. It was found that tinted windshields are associated with a variety of driver and vehicular variables believed to influence accident risk. Because of these uncontrolled, confounding variables, and because of methodological limitations associated directly with the CPIR fole, it is not possible to isolate the influence of windshield tinting in accident causation or prevention. A controlled study is recommended to make such a determination, possible within the National Accident Sampling System.

MEASURING VISIBILITY IN BLOWING SNOW

An electronic system that monitors visibility in blowing snow has been developed by the Forest Service, in cooperation with the Wyoming State Hwy. Dept., to help travelers avoid being standed in blowing snow storms and to improve the safety of transportation under drifting conditions. The sensor for blowing snow is a photoelectric particle counter that produces a voltage pulse for each snow particle particle counter that produces a voltage pulse for each snow particle which passes through a 3 mm by 25 mm area normal to the wind. The sensor's pulse train is processed electronically to give voltages proportional to five-sec averages of particle frequency and diameter. These voltages are combined with the signal from an anemometer in an analog computer which simulates visual range according to the equation, V equals 5U/F(X squared), where V is the visual range in m, U is windspeed in m/sec, F is the particle frequency in number/sec through a 1 sq cm area, and x is the particle diameter in cm. Field calibration was accomplished by a comparison with closed circuit TV recording of visual range targets during drifting. The correspondence between theory and observed visual range was very satisfactory, and two such systems are now in use for traffic control in Wyoming, having proved reliable and useful during three winters.

SYSTEM ANALYSIS OF THE GENERAL DETERRENCE OF DRIVING WHILE INTOXICATED

A system analysis indentified factors which influence DWI (driving while intoxicated), produced a system model of DWI general deterrence, examined the sensitivity of parameters relative to system outputs such as DWI trip rate and accident rate, and assessed countermeasure approaches. It was found that any significant reduction of DWI trips or related accidents must necessarily be effected through general rather than specific deterrence. DWI general deterrence depends critically upon drivers' perceived risk of DWI trips and on the risk aversion characteristics of potential drinking drivers. relatively small changes in perceived risk of DWI are likely to produce large changes in number of DWI trips/accidents. Word-of-mouth feedback from apprehended or sanctioned drivers is not likely to result in any significant reduction in DWI trips/accidents. Increased enforement reduces DWI trips/accidents significantly only when combined with increased information feedback of the consequences of these actions. The greatest potential for reduced DWI trips/accidents is through widespread dissemination of information emanating from effective and consistent DWI enforcement and adjudication actions. Research recommendations to supply needed information relevant to these conclusions are provided.

A PLAGUE ON THESE PESTS [INCONSIDERATE/UNSAFE DRIVERS]

By comparison with other European roadways, it is felt that British roads harbor some strange pests (i.e. irritating drivers); some of these obnoxious (and unsafe) driver types are described. One is the Limpet, or Bumper-Hugger, who sits inches from the bumper of the car he is following, matching the preceding vehicle's speed precisely; besides being offensive, his behavior is dangerous not only in failing to maintain a safe distance between vehicles but also in coercing the other motorist into dirving faster. The Ditherer pays far more attention to the other car occupants than to the traffic; he proceeds in fits and starts and does not use signals. The Road Hog charges into the safe distance between two cars in order to avoid oncoming traffic, and causes other drivers to brake heavily; he also flashes his headlights when he thinks the vehicle in front is holding him up. The Pig in the Middle, the driver who insists on occupying the middle lane at moderate speed, seems to be the pest who causes most trouble. The Litter Bug, the most widespread pest, is the driver or passenger who treats the highway like an unending trash can; he not only desecrates the environment, but also poses a threat to animals and persons on the roadside.

BIORHYTHMS AND TRAFFIC ACCIDENTS

A critical look at biorhythm theory, in particular its applicability to personal driver safety, is provided. The theory states that there are three fixed cycles in a person's life, each starting at the moment of birth (23-day physical, 28-day emotional, and 33-day mental cycles), and that each person is likely to perform well in the up phases, poorly in the down phases, and to be most vulnerable on the critical day, the midpoint of each cycle. These critical days are claimed to be most likley to be associated with accidents. Most information available about biorhythm theory is found in a book entitled "Is This Your Day?" by George Thommen, containing examples of studies mostly connected with accidents. Lack of convincing evidence for the theory; its shaky origin, being based on a German physician's subjective interpretations of mystical numbers; and the theoretical assumptions involved (that rhythms are invariant and start at the moment of birth) provide good reason for the skepticism that exists among the scientific community. The main advantages of the biorhythm theory seem to be the provision of extra income for an increasing number of entrepeneurs, and the satisfaction of its believers' need for "knowing" the future.

NATIONAL TRENDS IN BICYCLE ACCIDENTS

Two sets of data were collected and analyzed to estimate U.S. trends in bicycle accidents for the period 1973-1976. The first data source is the National Electronic Injury Surveillance System which contains data supplied by a national sample of hospital emergency rooms regarding visits due to product-associated accidents. The second data source comprises reports of 646 in-depth investigations of bicycle associated accidents conducted by theConsumer Product Safety Commission during 1962-1976. It was found that the type of injury and the population injured did not vary substantially over the time period involved. Similarly, the number of bicycle accidents did not increase significantly. With regard to product failure cases, it appears that a voluntary manufacturers' standard (Bicycle Manufacturer's Assoc./6) has reduced the incidence of frame failure; its possible effects should be investigated further.

EVALUATION OF PRODUCT SAFETY TEST METHODS: PROTECTIVE HEADGEAR

To demonstrate the effects of differing amounts of realism, the real-life simulation of head impacts (using a humanoid headform) was compared with a nonrealistic test method (using a rigid metal headform). Impact velocity was the same for both configurations; impact surface was varied in hardness to represent different (football) playing surfaces. The primary readout system was a Severity Index (SI) Analyzer that computed the resultant acceleration and gave a digital readout of the SI and peak acceleration. Using SI criteria, a mathematical relationship was developed for the pass/fail thresholds of the real-life simulation and the test method. Calculations were made on the efficacy of the test method in terms of acceptabel levels of discrimination of unsafe products (i.e. protective headgear such as football helmets), as well as the false alarm rate (rejection of safe products). The evidence suggests that test procedures using metal headforms correlate sufficiently well with real-life simulations using humanoid headforms to permit their use in consumer product safety testing.

PROXY MEASURES IN ACCIDENT COUNTERMEASURE EVALUATION: A STUDY OF EMERGENCY MEDICAL SERVICES

The necessity of establishing a relationship between a proxy measure used to evaluate a safety countermeasure and the ultimate objective of the countermeasure (reduction in accident frequency and severity) is demonstrated. Such a relationship is established for one severity-reduction countermeasure, emergency medical services (EMS), using Alabama accident data. The proxy measure utilized is ambulance response time, which is found to be related to fatality reduction. Additional analyses by time of day, day of the week, and month of the year demonstrate how additional information can be obtained using the proxy measure. Other proxy measures might be sought that, individually or in combination with delay time, could lead to greater insights into more effective EMS resource allocation.

THE CONGRESS NEEDS TO REDIRECT THE FEDERAL ELECTRIC VEHICLE PROGRAM. REPORT TO THE CONGRESS BY THE COMPTROLLER GENERAL OF THE UNITED STATES

This evaluation of the Dept. of Energy's (DOE) program to develop, demonstrate, and commercialize electric vehicles (EV'S) addresses the potential for EV'S to conserve oil and achieve other environmental objectives, DOE'S implementation of the three major program segments (vehicle demonstration, research and developement,and incentives for small business). Applicable legislation, reports, and planning documents were reviewed, and interviews were conducted with program managers within DOE and other organizations carrying out program responsibilities, officials of other government agencies, and representatives of the automobile and battery industries and EV producers. Although it is concluded that EV'S represent a technology meriting continued development, today's vehicles have limited commercial potential because they cost more and perform less efficiently than conventional vehicles. It is recommended that EV research and development be strengthened, that vehicle demonstrations be limited initially to the Federal sector, and that loan guarantees for commercial production be delayed. The Congress should make the legislative and other changes needed for program redirection. (A letter dated 10 Jan 1978, from DOE to the General Accounting Office, commenting on a draft of this report, is appended.)

ESTIMATES OF MAXIMUM ELECTRIC FIELD STRENGTHS IN THE AUTOMOBILE ENVIRONMENT

Strong electromagnetic (EM) energy sources are examined and estimates made of maximum EM field conditions to which automobiles could be exposed. The results are intended to alert automotive engineers to potentially hazardous EM radiation that might upset on board electronic control devices. The strong EM sources fall into the broad categories of broadcast radiation (AM, FM, TV and Mobile), microwave satellite communication and energy beaming, microwave radar (pulsed fields), high-voltage overhead power transmission line, and transients (radio flash) due to lightning and EMP (electromagnetic pulse) from nuclear explosions. Various expressions relating electric field strength (E) to distance from the source, transmitter power, antenna characteristics, etc., and a few supporting measurements are presented, as well as the maximum E for the automobile environment: For all common failure modes (e.g. thermal overload, burn out, dielectric breakdown, malfunction, bit error, and dropout), the strength E should be a realistic indicator of direct and indirect degradation energies. The conversion of the ambient E field into meaningful currents and voltages at the on-board electronics level has been a major difficulty and more research is needed to assure safe operation and to avoid costly overdesign.

DIESEL BUS PERFORMANCE SIMULATION PROGRAM. FINAL REPORT

A diesel bus performance computer simulation program provides information on acceleration, velocity, horsepower, distance traveled, and fuel consumption as a function of time from the originating station. Although the program was written for diesel engine operation, heat engines other than diesel may be substituted. Fuel economy calculations using the program agree well with available measurements on urban buses and may be considered representative of a baseline urban bus. Component submodels and vehicle coefficients have been carefully structured to represent current urban buses. A general description of the simulation program, the type of input data required, and results obtained by simulating a typical transit bus are provided.

THE CRASHER PAPERS: NOTES FROM THE DROP ZONE. SOMETIMES A LITTLE HURT CAN HELP [MOTORCYCLE ACCIDENT STATISTICS]

Some preliminary results are described of a study being conducted by the Univ. of California, under the sponsorship of the National Hwy. Traffic Safety Administration, which is investigating 899 motorcycle accidents occurring in Los Angeles during the past two and one-half years. More than half of the accidents studied involved riders between the ages of 16 and 23; and although women constitute only 2% of the motorcycling population, they accounted for 3.8% of the accidents in the study. Of the accident victims, 65% were not wearing helmets, 38% stating that they did not expect to have an accident. Over 494 of the accident victims did not have a standard motorcycle license. The average street-riding experience was nearly three years, but more than half the involved motorcyclists had less than five months experience; less than 10% had any formal motorcycle training. The 12% of riders using alcohol or drugs accounted for almost half of the fatalities; an equally small group who had more than four traffic violations in the previous two years represented 24% of the fatalities. In 45% of the accidents, a motor vehicle turned left into the path of a motorcycle, with visibility of the motorcycle a contributing factor. In evasion maneuvers, most motorcyclists tend to overbrake the rear and underbrake the front wheel, have increased reaction time over other motorists, and steer improperly. Misunderstanding of motorcycle dynamics which require an initial steering motion away from the intended direction, plays a large role in the accident victim's inability to react properly. When the rider hits the ground, full leathers are the best means of deceleration. Increased conspicuity (e.g. use of head lights at all times), wearing of helmets, thorough motorcycle training, and improved licensing procedures are advocated.

RV'S [RECREATIONAL VEHICLES]--THE COSTS OF OWNERSHIP

The costs of four modes of recreational travel (motor home, car and travel trailer, truck camper, and private automobile/motor hotel) are examined to compare the economics of self-contained recreational vehicle (RV) use vs. lodging and travel by car. Annual fixed (ownership) and daily variable (operating) cost estimates are compared for three RV types; average daily costs of transportation and lodging using a standard car (including a prorated share of ownership costs) are estimated. Estimates are based on results of interviews with RV dealers, repair shop supervisors, service mechanics, actual owners, and or cost figures obtained from insurance executives, banking loan officers, municipal authorities, campground managers, RV manufacturers, and various publications. A critical observation emerging from the analysis challenges the notion that RV owners are somehow "coming out ahead". In order for this to be true, the number of travel days per year would have to exceed the breakeven points of 335, 127, and 86 days, respectively, for the truck camper, the motor home, and the car and travel trailer. Few persons with full-time jobs are able to take that much time off for recreational use. The returns for RV owners must be found in intangibles such as expanded range of vacation opportunities, getting "back to nature", and sociability of fellow travelers. Indications are that the cost of owning and operating self-contained RV'S will continue to rise more rapidly than alternative modes of transportation and lodging. Consideration must also be given to possible stiff taxation on low-mileage vehicles and future gasoline rationing.

THE ELECTRICS ARE COMING! [ELECTRIC CARS]

Electric car development is increasing in the U.S., with manufacturers introducing all sorts of new models and stepping up research, and with the Federal government planning to spend $160 million between now and 1986 on electric vehicle (EV) research. General Motors unveiled one of its most advanced electric cars in 1978, the Electrovette (a modified Chevette), is now developing a highly advanced zinc nickel battery for future models, has several electric cars under test; and has just started making electric vans for American Telephone and Telegraph. General Electric (GE) has completed an experimental subcompact the Centennial Edition, with 60-mph and 75-mi-range ability. GE, along with Chrysler, is designing two other models for delivery to the Dept. of Energy (DOE) in 1979. Electric Auto Corp. (Detroit) plans to lease 300 units of its new electric model, the Silver Volt, to Fort Lauderdale, Fla., residents in a test program, and to install a system of quick-charge stations for everyday driving. If the program works, the company will go into production near the end of 1980; Electric Auto also plans to build an electric limousine Cadillac. U.S. Electricar Corp. has unveiled its 'Lectric Leopard which features an easy-to-plug in outlet for recharging. The Long Island Lighting Co. has just installed 40 more electrics in its fleet as a part of a DOE project, and is believed to be one of the world's major operators of electrics on public roads. The National Aeronautics and Space Administration has developed a nickel-zinc battery which offers possible 100-mi range

EUROPEAN BICYCLE SAFETY METHODS. THE WEST GERMAN WAY

The German education system incorporates a "Jugendverke hrsschule" or youth traffic school as a regular part of its fourth grade curriculm. The textbook used is the "die Radfahrpruefung", a bike textbook similar to a driver's manual, which prepares students for a written test on bicycle safety. There is also an instructor devoted exclusively to traffic safety tutoring. The near-zero rate of bicycle accidents among German children within the local area resulted in this system being adopted on a modified basis by the American elementary school at Hahn AFB, in the Hunsrueck area of West Germany. The school has adopted the German bicycle safety course and goals, condensed into a one-month period, and is taught to fifth graders. Receiving instruction from a member of the AFB'S Security Police Squadron, students are first introduced to the parts of a bicycle and required safety features. The initial theoretical portion of the course is presented, including a section on traffic laws and German traffic films, and a 40-point written test administered. Regardless of his test score, each student advances to the driving or practical portion of the program, taught by a German police officer who is an expert in traffic safety. Four separate traffic situations are taught, each on a different day, in a safe, school environment. In order to receive a passing grade, each student must complete the four exercises with a maximum of five mistakes. Students who complete the course receive a certificate and safety sticker for their bicycle. For the American school system as well as for German students, a near-zero bicycle accident rate indicates the success of the safety program.

DRIVER IMPROVEMENT--IMPROVEMENT OF DRIVING BEHAVIOR OF PARTICULAR MOTOR VEHICLE DRIVERS. EXPERIENCE AND THEORETICAL CONSIDERATIONS (DRIVER IMPROVEMENT--VERBESSERUNG DES VERKEHRSVERHALTENS AUFFALLIGER KRAFTFAHRER. BISHERIGE ERFAHRUNGEN AND THEORETICSCHE GRUNDLAGEN)

As part of a research project to develop appropriate rehabilitation measures for problem drivers in Austria, the theoretical foundation behind driver improvement, and international experience with driver rehabilitation are examined. Driver improvement measures as an extension of driver screening, and the provisions of Section 101 of Austria's Highway Code regarding driver competency are considered. Driving behavior as a learned behavior is analyzed; the role of feedback and reinforcement on behavior, types of behavior-regulating feedback to drivers (driving instruction, criticism by other drivers, punitive action by authorities for traffic violations, accidents and near accidents); and the effect of negative reinforcers (i.e. accidents and violations) on driving behavior are treated. The detection of problem drivers is discussed in terms of the relationship between a driver's traffic record and accident involvement, and the point systems (for traffic violations) in West Germany and the U.S. A summary of driver improvement measures, a comparison of different driver improvement group courses in the U.S., and an outline of driver improvement initiatives in German-speaking countries are provided. A critical evaluation is made of existing group programs for driver improvement, and the applicability of various forms of therapy to driver improvement is analyzed. A model plan is presented for the detection and rehabilitation of problem drivers in Austria.

MOTORCYCLE HELMET USE IN RELATION TO LEGAL REQUIREMENTS

Helmet use by motorcyclists was observed in late 1978 in cities of six states with varying legal requirements regarding helmet use. In two cities (Baltimore and Miami), in which all motorcyclists are legally required to wear helmets, virtually all riders wore helmets. In three cities (New Orleans, Phoenix, and Houston) where helmet laws requiring use by all motorcyclists were changed in 1976 or 1977 so that use is mandatory only for those persons under the age of 18, wearing rates were 39%, 46%, and 63%, respectively. In Los Angeles, which has never had a mandatory helmet use law, 46% of motorcyclists wore helmets. Based on these survey results, and on the known efficacy of helmets in reducing motorcyclist injuries, the repeal of helmet laws that occurred in 26 states in 1976-1978 can be expected to result in major increases in motorcyclist deaths in succeeding years.

LET'S REFRESH ON ALIGNMENT: 'CONSUMERS' VS. 'CROOKS' [WHEEL ALIGNMENT PRINCIPLES]

The basic principle of each front wheel alignment factor and the working relationship among these factors are explained for the wheel alignment specialist, including some inspection and adjustment tips. The following basic factors are discussed and illustrated: caster (forward or rearward tilt of the ball joints from a vertical line when viewing vehicle from the side), camber (inward or outward tilt of the front wheel from a vertical line when viewing vehicle from the front), toe-in (difference in distance between front and rear edges of front tires when viewed from topside of vehicle), toe-out on turns (degree difference in turning angle of two front wheels), king pin inclination (a locating of the ball joints so that they are "offset" from the vertical when viewed from the front of vehicle), and included angle (king pin inclination and camber together). Camber (and side to-side difference), caster (and side-to-side difference), and toe-in specifications are provided for the purposes of diagnosis for warranty repairs or customer paid service, periodic motor vehicle inspection, and resetting alignment. It is pointed out that of all front wheel alignment factors, toe or toe-in is probably the most important because of its immediate effect on tire wear. The importance is emphasized of checking a vehicle's riding height before checking or adjusting alignment, and making caster/camber adjustments only when necessary.

THE NSC [NATIONAL SAFETY COUNCIL] BIKE INSTRUCTOR SEMINAR: HELP FOR THE ROAD'S MOST VULNERABLE USERS

The National Safety Council's (NSC) 15-hour bicycle safety instructor seminars prepare individuals to teach not only the NSC All About Bikes Prog. (a comprehensive, six-hour course to give children the framework for wise bicycling), but also the 4-H Club and Club Scout bicycle training courses. The instruction is usually given on two days, broken down into four phases: a five-hour, classroom session in which the All About Bikes Instructor Manual is used as the basic text, supplemented by 4-H and Cub Scout Leaders guides; a two-hour session on bicycle maintenance and repair; a two-hour practice of the Skilled Driving Contest in which the instructor trainees actually practice the maneuvers they will teach their students; and a four hour session during which each of the student instructors takes turns teaching for from three to ten minutes. The eight skilled driving exercises cover balance ability, speed and slow speed coordination, decreasing space maneuvering, decreasing serpentine balance and steering, right or left evasion, and left and right spiraling. The final two hours are devoted to a "rap session", after which certificates of completion are presented. An important factor in the bicycle instructor seminar program is the inherent multiplying effect. In the fall of 1978, the NSC Youth Dept. sent questionnaires to 405 graduates (about half the total). Of the 61 who responded, more than 90% said that the instruction was sufficient to make them feel competent about teaching bicycle safety; each respondent was found to have taught, on the average, almost seven classes (215 per class). So far, 143 graduates of the seminar program have become certified instructor trainers. The seminars are organized by a "local catalyst" (e.g. safety council, police department, service club, PTA) who contacts the NSC'S Youth Dept. The basic fee is $13.50 per student; each class should have 25 to 50 students; equipment needed is a movie projector and at least three bicycles.

MINNESOTA TELLS PUBLIC: "REAL PROS DRIVE 55...SAVES GAS! SAVES LIVES"

In 1978, the Minnesota Safety Council, the Minnesota Dept. of Public Safety, and the Minnesota Energy Agency, initiated a public education campaign on the 55 mph speed limit, with a theme of "Real Pros Drive 55...Saves Gas! Saves Lives!". Three 30-sec TV spots were produced featuring champion professional racing drivers, and three more spots with national champion professional over-the-road truck drivers (provided by a cosponsor, the Minnesota Motor Transport Assoc.) which conducted a parallel campaign supplying literature and bumper stickers to its members, and forms to citizens for reporting speeding truckers). The highlight of the "Real Pros" campaign was in Jan 1979, when "The Minnesota Challenge" was broadcast throughout the state (estimated 120 million viewers), a half-hour energy-saving driving quiz program based on a Honeywell-produced film entitled "Featherfoot". Newspapers, magazines, and company publications published the program announcement and a quiz form and TV spots announced availability of forms; quiz forms were distributed to high school students as part of a home study assignment. Based on a major 1977 campaign on the 55 mph speed limit, billboard use was increased to 100 locations. The campaign slogan was used at public facilities and events. Eight prints of the "Featherfoot" were in constant circulation. An attitude questionnaire published in newspapers received a 50.58% extremely favorable response and 31.79% somewhat favorable response to the 55 mph speed limit; 48.41% responded that speeding was extremely important, and 30.79% stated that it was very important, in causing crashes; 72.11% believed that driving 55 mph saved gas, and 76.38% believed that it saved lives; but the majority believed that most people drove between 60 mph and 65 mph. Speed statistics for 1978 show that the "Real Pros" campaign assisted in holding speeds to a lower level than they had been in all years prior to 1977; but crashes and fatalities increased in 1978.

WHY NOT USE DRIVER LICENSE EXAM TO SCREEN FOR HEALTH PROBLEMS?

Dr. Patricia Waller, associate director for driver studies at the Univ. of North Carolina's Hwy. Safety Res. Center, proposes a low-cost, collaborative effort between driver licensing and public health agencies. The effort would involve using driver license programs to screen persons for the detection of certain health problems shown to be associated with poor driving (e.g. hypertension, diabetes), to refer those driver license applicants with problems to medical experts, and to follow-up the licensed drivers automatically every four years through renewal license procedures. The driver-related decisions would remain with the licensing authorities, while health and social service decisions would be made by appropriate professionals. The incorporation of such a screening program could be justified on licensing grounds; the relationship between hypertension and driving, for example, may prove to be more direct than that between vision and driving. (Vision screening is already a part of evaluation procedure for original licensure.) Departments of motor vehicles could also work cooperatively with state health professionals to control the problem driver. Health professionals and social services experts should play a major role in providing driver improvement analysts or state hearing officers (who frequently represent the first official personal contact with the department of motor vehicles for problem drivers) with information on community resources which could be used as additional alternatives to traditional driver improvement measures.

ACCIDENT INVESTIGATION--WHO CHECKS THE SHOCK ABSORBERS

Statistics accumulated over several years through independent tests and those from car clinics carried out by the European Shock Absorber Manufacture's Assoc. (EuSAMA) have shown that about one in three cars of testable age have one or more shock absorbers in a dangerous state of repair. Shock absorber wear is caused by outer-tube corrosion, damage by debris thrown up from the road, internal valve fatigue, and especially by deterioration of the oil seal resulting in hydraulic fluid loss. The wear and failure ratio is 60% on front axle, 40% on rear. EuSAMA classifies shock absorbers as dangerous when they are operating at 40% below original equipment figures. Shock absorber danger signs include hydraulic fluid on outside of absorber, loose absorbers, damaged end rubbers, badly corroded units, and bent piston rods (following accident damage). Worn shock absorbers affect headlight alignment, braking distance, and tire adhesion, in addition to ride and handling. Additional vibrations caused by worn shocks can cause car sickness and driver fatigue, can shake loose electrical components, wear tires unevenly, and wear out universal and drive joints and steering components more quickly. A suggested checklist for use by police at roadside safety checks includes observing the vehicle in motion (bouncing, lopsided attitude, headlight misalignment), bouncing the four corners of the car (check oscillations), and checking underneath vehicle for danger signs. The inclusion of shock absorbers in the Ministry of Transport Test in the U.K. in 1977 will do a great deal to eliminate worst cases, and has already resulted in increased shock absorber sales.

CAR REAR IMPACTS AND THE NEED FOR HEAD-REST

An analysis by the Transport and Road Res. lab., (TRRL, England) of 1971 road accident data for Great Britain showed that 5.5% (153) of fatal and 7.2% (2652) of serious car occupant casualties involved cars damaged in the rear. Of these casualties, almost 20% were rear-seat occupants who, according to other studies, had little need of headrests; over half of those injured in front seats were asymmetrically impacted from the rear, and narrow headrests might not have protected them. In 21 serious or fatal injury accidents investigated by TRRL which involved cars or vans struck in the rear, 7 out of 41 occupants suffered whiplash injuries, representing less than a quarter of front-seat occupants. A study by the Southern and Midlands Road Safety Units in 1969 found that 80 neck injuries occurred in 117 less serious rear-impact accidents. It is estimated that about 3% of all car occupants involved in rear impacts to their cars will suffer slight neck injuries (5% of all slight injuries) resulting in somewhat greater economic loss than for other slight injuries. Whiplash injuries from rear impact are thought to be somewhat greater than 5% of slight injuries. Detailed studies by TRRL have shown that whip lash injury does not correlate with extent of damage from rear impact. Whiplash injuries are caused by hyperextension of the neck, and are more likely to be serious for older people. Most experts consider headrests, high seat backs, etc., as means of preventing such injuries. A cost/benefit analysis suggests that the fitting of two extended seatbacks or headrests would have to cost 1 pound to equal benefits.

SAFETY EVALUATION OF PRIORITY TECHNIQUES FOR HIGH-OCCUPANCY VEHICLES. FINAL REPORT

Research focused on five major areas of high-occupancy vehicle (HOV) priority treatment projects: an examination of the pertinent accident rates, an analysis of causative factors influencing safety, an identification of difficult maneuvers and potential safety problems, the development of recommendations to improve safety, and a review of the legal authority and legal liability issues faced by HOV projects. Twenty-two HOV projects on 16 highway facilities were visited: Shirley Hwy., Fairfax Co., Va.; San Bernadino Freeway, Los Angeles; Moanalua Freeway, Honolulu; Santa Monica Freeway, Los Angeles; Route 101, Marin Co., Calif.; I-95, Miami; I-495, approach to Lincoln Tunnel, Hudson Co., N.J.; Long Island Expressway, New York City; ramp metering bypass ramps, Los Angeles; I-5, Seattle; San Francisco-Oakland Bay Bridge Toll Plaza, Oakland; Washington, D.C. central business district streets; U.S. 1/South Dixie Hwy., Miami; Kalanianaole Hwy., Honolulu; N.W. 7th Ave., Miami; and Ponce de Leon/Fernandez Juncos Avenues, San Juan, Puerto Rico. These projects encompass every type of preferential treatment strategy currently employed in the U.S. on both freeways and arterial facilities. For each HOV project, data on safety, operations, and geometrics were collected and analyzed. These data and qualitative information can be used to describe the current experience relating to the HOV safety issue.

ENGINEERING GUIDELINES FOR THE ANALYSIS OF TRAFFIC-INDUCED VIBRATION. FINAL REPORT

Guidelines are presented for assessing the potential for adverse environmental impact resulting from seismic vibrations induced by highway traffic. Vehicle/pavement interaction, propagation of vibration, response of building structures, and evaluation criteria are presented in quantitative engineering terms. Abatement strategies, measurement, and analysis of traffic-induced vibration are discussed. Example problems and analyses are presented for pavement surface roughness, vehicle speed, and vehicle gross weight, the main parameters in traffic induced vibration. The details upon which the guidelines are based are found in a parent report, FHWA-RD-78-168, "Determination of Impact from Vibrations Related to Highway Use," which documents a study to define the nature and extent of traffic-induced problems.

THE SURFACE TRANSPORTATION, ASSISTANCE ACT OF 1978

The Surface Transportation Assistance Act of 1978 (P.L. 95-599), signed into law on 6 Nov 1978, is the first act to combine authorizations for highways, highway safety, and public transportation in one piece of legislation, and the first act related to Federal-aid highways to authorize funds for a four-year period. Total funding provided in the act is $51.4 billion to become available in fiscal years 1979 through 1982, with $30.6 billion for highways, $7.2 billion for highway safety, and $13.6 billion for public transportation. The most significant provisions include extension of the Hwy. Trust Fund as the major source for highway and highway safety program funding for five years (30 Sep 1979 to 30 Sep 1984), as well as extension of existing taxes; stimulation of accelerated completion of the Interstate System; promotion of more effective safety and bridge programs; restructuring and refocusing of transit assistance; and program changes to promote greater flexibility.

FRONT DRIVE SYSTEMS FOR FOUR-WHEEL DRIVE LIGHT TRUCKS

The major components unique to light-truck four-wheel drive (4x4) systems and their effect on vehicle performance are reviewed. The tractive capabilities of four-wheel drive are compared with front and rear driver under various load, grade, and friction conditions. The effects of different types of inter-axle differentials are examined, and the advantages and disadvantages of various front suspension and drive systems for 4x4's discussed. Although significant technological advances have been made in the development of 4x4 systems, numerous aspects of current systems, such as ride, handling, cost, ease of operation, and fuel efficiency, compare unfavorably with their two-wheel drive counterparts.

AUTOMOTIVE SAFETY--THE NEED TO KNOW

It is emphasized that the consumer needs to be aware of present automotive safety standards and statistics in order to select a vehicle and equipment that will provide the greatest safety to him and his passengers. The greatest difference among vehicles in terms of occupant protection is related to vehicle size and weight. Statistics show a 3-to-1 ratio of death or serious injury to occupants of small cars over those of large cars; one study found that serious injury occurred twice as often when a small (compact) car collided with a small car as when a large car collided with a large car. It is questioned whether the fuel-saving 800 lb and 1000 lb weight reductions of new cars will offset the more sophisticated design for improved structural integrity and adversely affect the protectiveness of even the bigger cars. The consumer should be informed of the protection, comfort, and convenience afforded by the various restraint systems. The appeal of passive restraint systems is noted; because of their automatic operation, they eliminate many consumer information problems and require limited consumer cooperation. It is emphasized that these systems require honest, straightforward presentation and promotion, including mention of their disadvantages (e.g. initial and replacement cost of air bags, and force of blast on deployment). The need for more highway crash data on the effectiveness of air bags and passive belt systems is emphasized. The failure of Federal Motor Vehicle Safety Standard 121 (antilock brake systems for trucks and buses) because of inadequate evaluation in actual trucking service is cited, emphasizing the need for the consumer to insist that regulatory proposals remain proposals until field trials have been conducted. Automotive safety and safety regulation information on a much wider scale needs to be published to aid the consumer.

PERFORMANCE OF ALUMINUM AUTOMOTIVE RADIATORS

Field performance of flux-brazed aluminum automobile radiators removed from cars after service periods as long as ten years show aluminum to be a viable construction material. Data representing service experience dating back to the early 1950's indicate that properly designed radiators, adequately cleaned to remove brazing flux, offer a high degree of structural integrity. Extended, trouble-free service can be expected when cooling systems are maintained and the coolants added according to manufacturers' recommendations. With increasing usage of road salt during winter months, significant external corrosion of thin-wall tubes has been observed, but improved protective systems, now available or being developed, will substantially minimize the corrosion problem. Field experience with repair systems is limited, but laboratory tests indicate the availability of adhesive systems that should be adequate for repairing damaged radiators. Protective coatings are recommended for both metallic (lead tin) and adhesive (epoxy) repaired areas.

PERFORMANCE EVALUATION OF A VERSATILE TWO-CYCLE LUBRICANT ADDITIVE

Test data show that the performance of a new two-cycle additive (Additive A) is at least equivalent to the current Boating Industry Associations (BIA) TC-*W Reference Oil in water-cooled outboard engines operating on a variety of leaded fuels under a wide range of test conditions. Air-cooled engine performance was superior to the TC-*W Reference Oil in high-temperature ring sticking, and exhaust-port blocking, and the new additive system appeared to be effective in preventing piston scuffing during BIA TC-*W Phase 1 conditions. Additive A can be used to formulate TC-*W oils containing no bright stock. Limited lead-free fuel testing showed similar cleanliness and performance of Additive A. In certain high-output engines operating at 65:1 fuel-air ratio, it was found necessary to add 12% bright stock to the formulations to prevent piston scuffing and bearing wear. At 50:1 or less fuel-air ratios, no bright stock is required. The evaluation resulted in extensive test development using a large variety of two-cycle engines; this was necessitated by the lack of standardized certification procedures for air cooled, two-cycle lubricants. The BIA'S TC-*W test, although adequate to evaluate two-cycle oil performance in large-output outboard engines, cannot be expected to evaluate lubricants satisfying all engine types and operating conditions. Current efforts by the Society of Automotive Engineers, and the American Society for Testing and Materials to establish a meaningful two-cycle engine oil classification system are endorsed.

SAFETY OF MULTIPURPOSE VANS. SPECIAL STUDY

An investigation of 18 low-to-moderate speed crashes involving multipurpose vans was undertaken in order to determine injurious effects on occupants of custom interior furnishings and structural modifications, because certain existing Federal Motor Vehicle Safety Standards (FMVSS'S) do not apply to vans. The safety of vans was evaluated from the standpoints of injury-producing environment, occupant restraint, crashworthiness, postcrash fire, and ease or difficulty of escape. FMVSS'S 201, 202, 203, 204, 212, 214, 215, and 216 were evaluated in terms of these five main area of investigation. Inadequately secured or unsecured appliances, seats, and furnishings were found to have contributed to serious injuries and deaths. Securement of appliances and furnishings by wood screws, nails, or other fastenings is often inadequate to retain equipment in place during an accident. Custom highback bucket seats ("captain's type) failed in three cases and caused occupant injuries. Custom steering wheels caused injuries to several drivers and probably one driver death; some drivers were injured when they hit production steering wheels/columns. It is not clear that FMVSS'S 203 and 204 can be directly extended to vans. Restraint systems were not available or not used, partially accounting for a high number of ejections and severe-to-fatal injuries. Ten out of 19 vans did not retain their windshields on impact, resulting in five occupant ejections; FMVSS 212 applies only to forward-control vans. In five accidents, a van overrode a passenger car, resulting in four car occupant fatalities. Twenty percent of the doors jammed, not resulting in escape problems but posing a potential hazard. In six van models, not required to meet FMVSS 206, 17 doors opened at impact, while only two doors meeting the standard opened. No evidence was found of excessive passenger compartment compression, nor of adverse effects by custom windows on crashworthiness. Neither was there evidence that injury reducing features of FMVSS 201 (Interior Impact) would not have been effective in minimizing injury.

CHILDREN IN CRASHES: A SPECIAL ISSUE

Several current activities are reported involving hazards to children in motor vehicle especially, hazards to unrestrained children. The National Hwy. Traffic Safety Administration (NHTSA) regional workshops on child restraints are described; the first of these is planned for Atlanta in Mar 1979; the objective is to marshall grassroots support for increased protection for children in cars. Mention is made of NHTSA rules, to be issued in the summer of 1979, that will require dynamic crash testing of child restraints at speeds up to 30 mph, using specified test dummies. Although only one state now has a child restraint law in force (Tennessee), it is reported that proposed bills for such legislation have already been introduced in 11 states in 1979 and are expected to be filed in at least seven more states. A response by the Insurance Inst. for Hwy. Safety (IIHS) to an inquiry from a state motor vehicle administrator recommends necessary elements of an effective child restraint use law, and provides information on children in crashes. A cited study by the Univ. of Michigan's Hwy. Safety Res. Inst. (HSRI) found that many of currently used restraint systems for protecting handicapped children in school bus collisions are inadequate. A research project supported by IIHS demonstrated the inability of adults to restrain children adequately in their laps by holding on to them. Mention is made of a Dept. of Transportation order to review flammability standards for school bus interior materials. An IIHS-SUPPORTED study conducted by Johns Hopkins Univ. found that infants as motor vehicle occupants have an extremely high death rate compared to older children. The ineffectiveness of an Australian child restraint publicity campaign is reported. A letter to NHTSA from the IIHS concerns Renault's misinterpretation of Head Injury Criterion data from a free-fall study conducted by HSRI under IIHS sponsorship.

HS-026 121

UNSAFE AT ANY AGE? CHILDREN AND CAR SAFETY

Facts are reported about child involvement in motor vehicle crashes, with special emphasis on the importance of properly using appropriate child restraint systems. Various studies are cited which have demonstrated the effectiveness of child restraints in reducing injuries and fatalities in motor vehicle crashes, the number one cause of death for children over the age of one. Various statistics indicate the infrequent, and generally incorrect, usage of child restraint systems. It is recommended that in the absence of a child restraint device, small children should be made to use regular lap seat belts with the seat belt across the top of the child's thighs. Older children should use both lap and shoulder straps. The safest location is in the middle of the back seat. While an adult seat belt restraint is better than none, the first and best choice for a small child is an approved child restraint because it is designed to meet his special needs in a crash. Four types of child restraints include an infant carrier, a protective shield, a traditional car seat, and a safety harness. The Tennessee mandatory child restraint usage law exempts older children and allows parents to hold their children, a dangerous practice. The National Hwy. Traffic Safety Administration's proposed new testing and performance requirements for child restraints, and its regional child restraint workshops are mentioned. A "no excuses" safety guide for parents, and statistics from NHTSA'S Fatal Accident Reporting System on characteristics of accidents involving child fatalities, are outlined in separate sections.

BRIDGING THE GAP BETWEEN DEXTRON-II AND TYPE F ATF [AUTOMATIC TRANSMISSION FLUIDS]

An automatic transmission fluid (ATF) has been developed which can meet the needs of transmissions designed for either friction-modified or nonfriction-modified fluids. Approved under General Motors' DEXRON-II and Ford's M2C138-CJ specifications, it also meets the requirements of Ford's M2C33-F (Type F) specification except for the friction modifier content. The DEXRON-II/CJ fluid did not show any signs of clutch plate damage or band slippage when tested in transmissions designed for Type F fluid. The tests included severe, 8000-cycle vehicle and dynamometer tests and special vehicle dynamometer tests run by Ford. In actual field practice, DEXRON-II fluids are being added to transmissions designed for Type F ATF. Conversely, Type F fluids are being added to transmissions designed for DEXRON and DEXRON-II is superior to that of Type F ATF. As measured by the Turbo Hydramatic Cycling Test, the oxidation stability of Type F fluids ranges from nearly equivalent to significantly poorer than DEXRON-II requirements. It is believed that a specification designed around the DEXRON-II specification can be developed to describe a service station ATF that will be suitable for automative automatc transmissions which now require DEXRON, DEXRON-II, Type A Suffix A, or Type F ATF. Test results are appended.

AUTOMOTIVE TECHNOLOGY PROJECTIONS

Results of an automotive technology assessment study are presented to provide a basis of comparison for vehicles with alternative power systems. The following engine types are examined: Otto (uniform-charge (UC), rotary UC, stratified-charge (SC), rotary SC), diesel (naturally-aspirated, turbocharged), free-turbine Brayton (metal, ceramic), single-shaft Brayton (metal, ceramic), and Stirling (metal, ceramic). Factors considered include fuel economy, exhaust emissions, multifuel capability, advanced materials, and cost/manufacturability for both convention and advanced alternative power systems. to ensure valid comparisons of vehicles with alternative power systems, the concept of an Otto-Engine-Equivalent (OEE) vehicle is utilized. Each engine type sized to provide equivalent vehicle performance. Fuel economy projections are made for each engine type considering both the legislated emission standards (0.4 g/mi hydrocarbons, 3.4 g/mi carbon monoxide, 1.0 g/m nitrogen oxides (NOX)) and possible future emissions requirements (0.4 g/mi NOX). The sensitivities of the fuel economy projections to factors such as engine torque boundary, rear axle ratio, performance criteria, and engine transient response are discussed Using the OEE vehicle concept, projected fuel economies of both small- and full-size vehicles with Stirling engines are up to 40% better than baseline vehicles with conventional engines. Vehicles with Brayton engines show up to a 30% better fuel economy than the baseline in full-sized vehicles, but offer little fuel economy advantage in small vehicles. Advanced continuous combustion power systems (Brayton and Stirling) offer advantages over the baseline vehicles in the areas of exhaust emissions and multifuel capability, but their initial costs are projected to be substantially higher.

SMALL CAR SAFETY IN BIG-CAR COUNTRY

The safety aspects of roadside appurtenances which have been developed during the past ten years are reviewed, as well as those of systems currently under development and test. These systems, developed through research sponsored by the Federal Hwy. Administration, the states, and the private sector, are basically fail-safe systems designed to reduce fatalities, personal injury, and property damage in low- and high-speed impacts by either small or large-size passenger cars. The following categories of roadside appurtenances are covered (photographs of the fail-safe systems provided): luminaire supports, utility poles, roadside sign supports, overhead sign bridge structures, protective median barriers, impact attenuators at exit ramps, forgiving bridge rails, construction zone safety devices, railroad/highway grade-crossing environment improvements and impact attenuators, and tollgate facility impact attenuators.

EFFECT OF MAIN FACTORS ON DYNAMIC PROPERTIES OF MOTORCYCLE TIRES

Results are presented and discussed from a laboratory study undertaken to clarify how various tire conditions, such as internal pressure, load, make, width, tread pattern, and tread curvature, and the drum curvature of the testing machine, influence the dynamic properties of motorcycle tires. The importance of tire dynamic properties in predicting the dynamic properties of motorcycles, and the indispensability of the control of tire dynamic properties for the improvement of motorcycle performance are considered. It was found that tire dynamic properties (cornering stiffness, camber stiffness, side force (camber thrust), overturning moment, self-aligning torque) are significantly influenced by the various tire and drum factors. It is hoped that the beneficial data obtained may contribute to future improvement in motorcycle dynamic properties as well as in tire dynamic properties.

MOPED DIRECTIONAL DYNAMICS AND HANDLING QUALITIES

A comparison of moped and motorcycle design features related to directional handling is presented. Design parameter values are given for four sample mopeds (typical moped, moped with the appearance of a small motorcycle, moped with swing-arm front suspension, and moped with front-wheel drive (fork-mounted motor)), in comparison to those of a lighweight street motorcycle. Analytical results describing the sample mopeds' lateral-directional dynamics are provided. Using a nominal moped example, the sensitivity of the vehicle dynamics to operational and design variables, such as speed, loading, and tire properties, is shown. Implications for rider/moped handling are reviewed. Comparison of the four example mopeds with a lightweight motorcycle and other street machines shows that the mopeds generally have response modes similar to motorcycles, but that mopeds can be twice as sensitive to roll-to-steer torque gains at nominal operating speeds, requiring more precise control and attention, and reduced inadvertant control activity. Factors are outlined which reduce moped stability in the capsize, weave, and wobble modes.

SIMULATION OF OFF-ROAD MOTORCYCLE RIDE DYNAMICS

Previous work on vehicle ride dynamics applicable to motorcycles is reviewed, and the basis discussed for a four-degree-of-freedom (bounce, pitch, and movement of each wheel) computer simulation of the dynamic ride response of a motorcycle. The simulation is nonlinear in terms of both geometry and suspension components, and is generally applicable to any type of motorcycle of reasonably standard configuration. It was developed in the context of application to off-road motorcycles, and special problems associated with simulating these machines are discussed. Some numerical results are presented which indicate that the dynamic response is strongly nonlinear, with wheel lift-off and suspension bump stops as the two major sources of nonlinearity. Considering the general behavior of the stock vehicle utilized (a 1974 Kawasaki KX250 typical motor-crosser), it was found that instead of two separate bounce and pitch natural frequencies, one general resonance at around 5 cps occurred, indicative of the strong coupling between bounce and pitch for this vehicle. The accelerations at 5 cps were much stronger for the out-of-phase sinusoid than for the in-phase case, suggesting that a pitching motion (arising from out-of-phase case) is more uncomfortable for the rider. Recommendations are offered for improving the simulation.

MOTORCYCLISTS' VISUAL SCANNING PATTERN IN COMPARISON WITH AUTOMOBILE DRIVERS'

Three male subjects participated in experiments in which an eye-marker method was used to compare motorcyclists' vs. drivers' visual scanning behavior. Independent variables were vehicle type and speed. The proportion of road surface in the visual field was found to be much larger for the motorcyclist than the driver of the car. Since the motorcyclist's head is tilted forward, it follows that he is apt to be looking at the near road surface more frequently. From an analysis of motorcyclist and driver fixation points, it is suggested that the motorcyclist is acquiring information mainly from the near road surface, whereas the car driver is acquiring information mainly from the distant foreground. For motorcyclists, the vertical variance of visual field and fixation points is larger, suggesting that the motorcyclist is trying to acquire information from both the near road surface and the distant foreground. Mean fixation duration of the motorcyclist is shorter than that of the car driver, suggesting that the cyclist is acquiring and identifying information relatively superficially. These findings have implications for motorcycle accidents in which the cyclist fails to detect vehicles turning left, oncoming vehicles, crossing vehicles, and pedestrians. Motorcyclists, automobile drivers and pedestrians should all be informed of these facts.

HS-026 292

PRODUCT LIABILITY AND THE MOTORCYCLE DESIGNER

Recent changes in product liability law, and in the magnitude of jury awards, dictate that motorcycle designers shift their design priorities. Since a relatively recent California court decision (the Ault decision), a designer must approach development of new products, or new models of and existing product, with the full knowledge that if he creates a safer design than his company previously manufactured and sold, all previous products may be judged in accordance with the safety or performance of the new, improved version. The Barker vs. Lull decision (early 1978) effectively eliminates most of the previous burdens of proof from the plaintiff in a product liability case. To the other costs of a motorcycle design, costs of insurance and/or directly paid litigation costs must be added. If enormous "punitive damage" claims continue, which is indicated, it will be incumbent upon the motorcycle designer to consider how much exposure, or potential liability, a particular design might represent in court. If a little more money must be spent in a design to reduce potential product liability exposure, then this expense must be evaluated in light of potential financial and adverse publicity losses in court. The astonishing increase in out-of-court settlements is related to the increasingly liberal interpretation of product liability laws by the courts, and the tremendous rise in defense costs. Product liability litigation demands serous consideration by the motorcycle designer at the concept stage and throughout final hardware development.

EXPERIMENTAL STUDY ON MOTORCYCLE STEERING PERFORMANCE

Experiments on four large (650 cc to 900 cc) motorcycles of Japanese manufacture to study machine lateral motion involved analysis of pulse response, high-speed random response, and land-change response (straight or near-straight course runs), and ramp step response and slalom response (curved course runs). Results of each experiment were arranged as frequency response functions (input, output) by random signal analysis. Three primary oscillation modes (capsize, weave, and wobble) were studied. Steer torque and rider lean angle were considered as independent rider control inputs, and both single-input and dual-input analyses were conducted. The major input factor was found to be torque, with lean angle by itself having almost no influence on output.

HS-026 294

EXPERIMENTAL INVESTIGATION OF THE TRANSIENT BEHAVIOR OF MOTORCYCLES

Analytical and experimental studies investigated the transient and oscillatory behavior of three example motorcycles (lightweight, intermediate, and heavyweight). The effects of adding load, changing operating conditions, and modifying vehicle configuration were examined. It was found that adding a rear load of 10% gross vehicle weight can lead to weave oscillations in some cases, particularly in near-limit, steady turns where the suspension is compressed and the normal load on the tires is greater; the rear load plus the weight of the rider and instrumentation, can bottom the suspension in extreme cases. Analyses showed that adding a large, rear load can also decrease the wobble mode damping. Damping rear suspension motions can reduce or eliminate the cornering weave problem, consisting of coupled lateral and longitudinal motions in a particular speed range. Adding weight to the front fork assembly ahead of the hinge line increases the mass and steer moment of inertia; this tends to decrease both weave mode damping and natural frequency. The presence of a fork-mounted fairing transmits aerodynamic forces and moments directly to that assembly. Aerodynamics disturbances can apparently excite the wobble mode at high speed, while the corresponding no-fairing case has no wobble oscillation. The fairing tends to decrease the wobble mode frequency somewhat. Oscillatory behavior existed only when one or more of the following conditions were present: very high speeds, adverse loadings, hands-off operation, near the limit of performance (e.g. in a high lateral acceleration, steady-state turn), and degraded components (e.g. shock absorbers). the cornering weave phenomenon tends to arise in high lateral acceleration, steady turns when the weave mode natural frequency (which is speed-dependent) is in the vicinity of the pitch mode (rear suspension) natural frequency. The lean angle is sometimes determined by ground clearance. A large steer torque pulse sometimes excites a persistent directional oscillation, not otherwise present.

ACCIDENT AVOIDANCE CHARACTERISTICS OF UNCONVENTIONAL MOTORCYCLE CONFIGURATIONS

Low-center-of-gravity, long-wheelbase motorcycle configurations were investigated analytically in terms of stability, obstacle avoidance characteristics, and braking performance, using mathematical models of both the uncontrolled and rider-controlled motorcycle. Both front- and rear-steered configurations were studied. The rear-steered configuration was found to have unacceptable stability and controllability characteristics; this was confirmed by tests on a buck. On the basis of the analytical results, the front-steered configuration appears to have an advantage in improved obstacle avoidance performance at other than very low speeds, with stability at least equal to a conventional machine. Another potential advantage is in reduced sensitivity of the front-to-rear brake proportioning to lateral acceleration and road conditions. Offsetting these advantages to a degree are a degradation in low-speed manueverability and controllability, and weight and overall complexity of the machine.

WHAT'S NEEDED TO MAKE RRIM [REINFORCED REACTION INJECTION MOLDING] A BETTER BET FOR THE AUTO INDUSTRY

The development program in RRIM (reinforced reaction injection molding) established at Ford Motor Co. in Jul 1977 to investigate the suitability of the process for molding automotive exterior body panels is described. The four main areas evaluated are equipment capability to handle reinforcing agents (monitored for relative degrees of abrasiveness, settling, and clogging characteristics); fiber reinforcements and their effect on coefficient of linear thermal expansion (CTE); processing characteristics of fiber-filled materials (viscosity, cycle time); and physical properties of the high-modulus and rigid RIM materials (automotive Class-A surface, heat sag, impact strength, CTE, fiber orientation, flexural modulus, paintability). The RRIM trials and material testing indicate that RRIM is already a feasible process for exterior body panels requiring a Class-A surface finish. Further improvements needed in the process include internal mold release, light-stable substrates, heat stability at 400 degree F, mixing head to handle abrasive slurry, and advances in fiber technology. Future developments in the field of polyurethane (PUR) and non-PUR materials combined with milled and/or chopped fibers and other fillers could make the RRIM process a candidate for structural members.

ROADSIDE RIPOFF [DISHONEST PRACTICES BY SERVICE STATIONS]

Advice is given to the motorist on how to combat the dishonest practices of unscrupulous service station attendants (estimated at 2%) who try to sell drivers unneeded products or services. Regular car maintenance by a reliable mechanic and learning as much about one's car as possible are recommended. When a problem is reported by an attendant, the motorist should examine the reported defect, and should act as if he understands the problem; if the mechanic uses technical jargon, the motorist should insist on a simple explanation. It is emphasized that emergency repairs should not be authorized hastily; a second opinion should be obtained if possible. A damaged tire should be changed, but a spare will probably work adequately for a short distance; a set of tires should never be bought from an out-of-the-way station. If a decision is made to have a repair done, the car owner should find out what is involved in the procedure and how much it will cost before the work is started. A signed, detailed receipt and the bad parts should be obtained. When paying for gasoline, oil, and other services, the motorist should be certain about the currency tendered, should count his change, and should walk to the credit card imprinter with the attendant and read all invoice slips carefully. If the motorist feels cheated, he should write a letter(s) to the oil company involved, an auto club, attorney general's office, and/or the state's consumer affairs office.

THE USED-OIL RECYCLING PROGRAM

To eliminate the environmental hazards of improper disposal of use motor oil, the California Legislature passed the Used Oil Recycling Act in 1977. The bill (SB 68) appropriated $100,000 to the Solid Waste Management Board to set up collection stations for used oil, to adopt a set of rules governing the collection and disposal of that oil, and to educate the public on the merits of the reclaimed product. Solid Waste Management has now organized a network of over 2000 collection facilities (automotive service stations, auto repair shops) throughout the state where the do-it-yourself oil changer can deposit the drainings. All used-oil receiving facilities have signs posted announcing their participation, and any retailer selling motor oil for off-the-premise use is required by law to post a sign indicating the location of a nearby collection facility. Donors are not currently paid for the used oil; collection stations receive 5 cents/gal from oil re-refiners for the used product (about 30 million gal of crankcase oil presently recycled annually). About 80% of the motor oil is currently being reclaimed, 10[illegible] million gallons as crankcase oil, 13[illegible] million gallons as fuel oil, and 6 million gallons as road oil or asphalt. Among the available reclaimed motor oils, which must meet Federal quality standards, are Mor-Lube, Rexol, and Modern. Various truck lines and taxi companies, as well as the City of San Diego, are using re-refined motor oils in their fleets. The Calif. Dept. of Transportation is conducting a test program of fleets using the recycled oils. Solid Waste Management hopes that at least half of the 80 million gal of motor oil sold annually will be re-refined.

LEMON AID [ADVICE ON BUYING A USED CAR]

For prospective purchasers who are not versed in mechanics, suggestions are provided for avoiding mistakes in buying a used car. The first step is to make a firm decision on type of vehicle wanted and affordable price. Among sources of used cars, consideration should be given to the newspapers' want ads, and other sources (auctions, sales lots of big car rental agencies, new-car trade-ins on dealers' lots). Dealers' warranties should be examined critically. A thorough examination should be made of a prospective purchase, including a walkaround, a drive, and a mechanic's inspection. Walkaround checks include the paint job (look for blisters, and if exterior paint matches interior spots, e.g. trunk), odometer reading (over 10,000 to 12,000 mi/yr is excessive, much less than that indicates excessive city driving), driver's seat and pedals (if newer than car, could indicate rough use of vehicle), tires (for even wear, and matching), shock absorbers (bounce test), latches (locked and unlocked), brake pedal, under the hood (especially for leaks), and engine-start conditions (gauges and lights on panels, abnormal sounds, color of exhaust). The driving test checks include steering wheel play; gear changing for automatic and manual transmissions; wheel alignment (check for turn-in, turn-out, or wobble while someone else is driving); firmness of accelerator, brake pedal, and clutch; and working order of all controls, signal lights, buzzers, and gauges. The final inspection should be by a reliable mechanic.

A MICROPROCESSOR-BASED SYSTEM FOR TRAFFIC DATA COLLECTION

The design and construction are described of a system to collect traffic data and transfer them to a central computer for processing, as well as the recent use of the new system in observations of traffic behavior at T-junctions. A comparison is made with an earlier system which involved videotaping of T-junction traffic behavior, incorporating a digital clock image, analyzing the tapes in slow motion and noting the event and clock time, transferring the output (a list of events and times to the nearest tenth of a second) to punched cards, and analyzing by computer. The new microprocessor-based system was sought to reduce the time and effort required by using data input manually by observers and data from automatic sensors. The data collection equipment is the Golden River mk4 system, a modular system based on a microprocessor. It has facilities for using random access memory and programmable read-only memory, a real-time clock, a number of input and output facilities, and its own power supply. Analysis of traffic data using this system is comparatively easy and much quicker than video techniques. The accuracy of the data is limited by the accuracy of observers in a real-time situation. The equipment, although fairly bulky, is portable; a second smaller version is being designed. The system could be used for other data collection purposes and could be adapted for many computing tasks.

LABOUR-SAVING METHODS FOR COUNTING TRAFFIC MOVEMENTS AT THREE-AND FOUR-ARM JUNCTIONS

Mathematical analysis demonstrates how the suitable placing of automatic traffic counters can reduce the number of traffic observers required for recording vehicle turning movements at intersections. Equations are derived and applied for traffic counts at three- and four-arm junctions. Three options are studied for a crossroads situation; it is assumed that the proportion of traffic from one road turning right is known, that the proportion of traffic from one road that goes straight onto another road can be estimated or that the proportion of traffic from one road that will turn left can be estimated. It is shown that by an appropriate choice of option and use of local knowledge (e.g. that there is no right turn) or historical data, good estimates, even 100% accurate results, may be obtained, using fewer than one observer per arm at an intersection. It is shown that if a certain value cannot be estimated, its value can be limited to a practical range and hence the largest practical range of values can be found for the traffic flow.

HS-026 303

A ROAD TRAFFIC SIMULATOR EMPLOYING MICROPROCESSORS

A new hardware/software road traffic simulator employs microprocessors in a parallel configuration. Each of two microprocessors simulates the performance of each intersection in a traffic network with a further microprocessor as an overall controller. With each one of the set of microprocessors operating essentially in parallel, organizational problems are minimized, and overall speed is no longer a function of network size. The degradation of speed as the network size increases is minimal. Input and output of traffic data are facilitated through the use of a minicomputer equipped with visual display unit and cartridge-disc store to which the hardware model is attached as a special-purpose peripheral. This approach facilitates overall control and the application of appropriate traffic signal control policies. If simulation speed is high, it also provides the possibility of predictive control policies. Cost considerations have restricted the model to a small size, although the modular structure allows easy expansion.

TURBOCHARGING: WHAT DOES THE FUTURE HOLD?

Various approaches and options in the design of automotive turbocharges are discussed. The movement to backswept impeller blades in the new small units is considered. Means of avoiding overboosting the engine at high engine speeds (exhaust wastegate, adjustment of the turbine nozzle flow area) are outlined. Two-stage turbocharging (i.e. two turbo units placed in series) is mentioned as a design option. The Hyperbar system is cited as an example of an approach to maintaining high turbo speeds by the use of exhaust augmentors or combustors. The application of turbocharging, and associated problems, to diesel passenger cars and gasoline engines are discussed. It is felt that if low-priced turbochargers become available in mass production for the gasoline engine, they will undoubtedly be used on many passenger car diesels. Technical work in progress relates to turbocharger reliability and installation, fuel system control, boost pressure control, increasing low-speed boost, and reducing turbo lag. Placement of the throttle before or after the turbocharger compressor in a gasoline engine and its effect on compressor efficiency are discussed. A comparison is provided of the advantages and disadvantages of positioning the carburetor either upstream or downstream of the compressor section.

AERODYNAMIC DESIGN BOOSTS FUEL ECONOMY AND ROOMINESS

Design of General Motors' 1980 front-wheel-drive X-cars demonstrates that substantial fuel economy improvements can result from aerodynamic studies at the beginning of the design cycle. Fuel economy gains from aerodynamic drag reduction are equivalent to a weight loss of about 118 kg via downsizing or lightweight material substitution. The average coefficient of drag of the 1980 X-cars (0.442) is 0.070 lower than the average of 11 domestic and import family-type cars measured, and only 0.016 higher than the average of eight sports cars. The aerodynamic drag force (proportional to drag coefficient times frontal area) of the 1980 X-cars also compares favorably with the same 11 family-type cars. The lower drag coefficient and frontal area of the 1980 Chevrolet Citation 4-door hatchback vs. the 1979 Nova 4-door sedan result in a saving of 1.4 mpg composite fuel economy at a level of 25 mpg. Improvement in aerodynamic drag (1.2 mpg) is the largest source of mpg improvement other than the 363 kg weight reduction. The improvements were quantified in a computer simulation, "GPSIM." The aerodynamic program had five basic stages, beginning with the development of a basic overall appearance theme of the car compatible with low aerodynamic drag. Both 1/4- and full-scale clay models of each X-car division (Chevrolet, Pontiac, Oldsmobile, and Buick) were tested, followed by tests on prototype and pilot line cars. Pros and cons of testing quarter-scale and full-scale models are tabulated. After wind tunnel testing, each of the prototypes was given a coastdown test. The three-year program ended with a coastdown testing of pilot line cars. Four other design goals involving aerodynamics were ample radiator flow for engine cooling and minimizing electric fan running time, reduced wind noise at windshield pillar and side mirrors, minimum side glass contamination from road splash, and adequate ram air ventilation of the passenger compartment.

CHEVROLET DESIGNS AND BUILDS A NEW V-6

The Chevrolet Div. of General Motors (GM) was assigned design and manufacturing responsibility for a v-6 powerplant which would provide optional extra power and performance for GM'S 1980 x-car program. The engine is currently available in the Olds Omega, Buick Skylark, and Pontiac Phoenix, as well as the Chevrolet Citation. The 60 degree v-6 engine is placed transversely in the vehicle, with the flywheel on the driver's side. Since vehicle packaging was established by the time a firm decision was made to design an optional engine, the engine compartment dimesions were well-defined, adding space constraints to the other reasons for a 60 degree bank angle. Overall width of the engine with accessories is 657 mm or 101 mm less than that of the Chevrolet 90 degree v-6. Overall engine length is 536 mm; the electrically-driven cooling fan is mounted to the radiator support structure, rather than the engine. Although cast iron was used for both block and heads, the design philosophy was to minimize weight. The v-l, 2.8-L engine is tuned to deliver 86 KW (115 hp) at 4800 rpm and 196 N.m (145 lb. ft) at 2400 rpm, the actual torque curve being flat and broad. Because of the shape of the power curve, wide-open-throttle shift speeds with automatic transmission are calibrated to 5300 rpm, 500 rpm over the peak, but a speed which delivers greater vehicle acceleration. The vehicle, equipped with v-6 and automatic transmission, is estimated to deliver 20 mpg city, 30 mpg highway, and 23 mpg combined.

GM ACHIEVES FUEL ECONOMY VIA SYSTEMS ANALYSIS

techniques for optimizing fuel economy in the design of General Motors' 1980 front-wheel-drive X-cars involved reduction of road load and parasitic losses combined with powertrain matching to the vehicle as a system. Initial parametric studies, using the GPSIM simulation program in the concept definition stage, indicated many fruitful areas for fuel economy improvement (e.g. reduction of aerodynamic resistance, tire rolling resistance, and brake drag; optimization of gearing). Using GPSIM, each component of the vehicle and the power transmission system was analyzed to determine accurately the effect of a change in that parameter on fuel economy. Optimization of the vehicle as a system required that the most influential subsystems have characteristics which could be relied on to perform predictably in the final car in order to avoid mismatching of powertrain parameters to the vehicle. Target characteristics affecting economy and performance were defined, usually preceding the actual design. With definition of basic vehicle parameters (e.g. frontal area, weight distribution), and with targets for mass, aerodynamic drag, and tire losses, powertrain matching analyses were made of transmission gearing, torque converter characteristics, final drive ratios, and engine displacement requirements to meet performance targets. Each component was also examined to minimize its parasitic losses. The result of the fuel economy optimization program is the base engine 1980 X-car with automatic transmission having a composite fuel economy rating of 26.7 mpg, a 37% improvement over the 1978 X-car (19.4 mpg); while about 3.6 mpg were gained directly from reduced size and weight, the remaining 3.7 mpg resulted directly from road load and parasitic loss decreases and powertrain optimization.

AN UNCOOLED, UNLUBRICATED DIESEL?

High-performance ceramic materials may eventually permit designers to omit cooling and lubrication system from heavy-duty diesel engines. If current research and development programs are successful, it may be possible to produce an uncooled diesel engine of high thermal efficiency in conjuction with turbocompounding. Through the use of turbocharging to compensate for decreased volumetric efficiency, and a turbocompounding device to convert the increased exhaust energy of a hot adiabatic engine to useful power, improved thermal efficiencies result. With the hot adiabatic engine concept, the cooling system is completely eliminated. The minimum-friction unlubricated engine may be made possible with high-performance ceramics, but according to Cummins Engine Co. and the U.S. Army Tank Automotive Res. and Devel. Command, no present high-performance ceramic can fulfill all the required properties for the diesel engine. zirconia and lithium aluminum silicate glass ceramics feature low cost and ease of process control, but lack the high strength required for the diesel. A laboratory adiabatic diesel engine has been designed and built around Cummins' six-cylinder NH engine in order to demonstrate technical feasibility of an adiabatic turbocompound engine of advanced ceramic design. Three cylinder builds of the basic engine were made, each emphasizing different materials (metallic, hot press silicone nitride (HPSN), and glass ceramic). The high-strength, high-temperature true capability of HPSN offers the best chance of success during preliminary feasibility demonstration.

FRICTION MODIFIERS TAILOR BRAKE AND CLUTCH CHARACTERISTICS

New requirements for friction lining materials exist because of the elimination of asbestos in brake and clutch compositions and the use of small pads for downsized and compact cars. Research on solid friction control additives at Dow Corning Corp. has produced new technology by which friction and wear properties can be tailored to specific requirements. Compositions of phenolic resins (binder in friction composites) with high loading of molybdenum disulfide, MoS2 (European use as friction modifier) and Dow Corning's Friction Modifier "A" were tested on an Alpha LFW-1 friction and wear testing machine. Addition of either friction modifier provided a reduction in wear and friction; the resin with "A" gave generally lower initial coefficients of friction and wear values and changed less with time. Friction Modifier "A" gave a more constant coefficient of friction with changes in speed, load and time. At higher speeds and lower loads, no difference in wear was apparent between MoS2 and "A". Good correlation was found between LFW-1 test results for three different brake compositions (Class A, high in asbestos and organic components; Class B, less asbestos and organic components plus some inorganic components; and Class C, semimetallic nonasbestos composite) and their general characteristics. Class C gave the most stable frictional properties, but also produced the most noise. Addition of 10% Friction Modifier "A" to Class C resulted in more consistent coefficient of friction properties between 600 and 1200 rpm, and less noise. Comparisons between the new friction modifier and MoS2 in brake pad Compositions during dynamometer testing showed the following advantages for the new additive: lower noise, less dependence of friction coefficient on temperature, decreased wear of brake pad (30% increase in lifetime), and decreased wear of metal disc.

AIRBAG GAS GENERANT SIDE EFFECTS STUDIED

The all-chemically-generated gas system (pyrotechnic) of air bag restraint systems (ARBS) contains sodium azide as the propellant. Unburned sodium azide is apparently toxic to humans, animals, vegetation, and microorganisms in small concentrations; long-term effects are not well-known. When the compound burns, it produces harmless nitrogen and small amounts of strongly alkaline Substances, which in normal air bag deployment do not reach the passenger compartment. The DL-*Z113 propellant based on sodium azide is classified as a Class C explosive. The hybrid ABRS uses stored gas (argon) supplemented by propellant (potassium perchlorate with polyvinyl chlaride and cabon black). The dosages of this propellant resulting in adverse health effects are much higher than any intake which might occur with its use in air bag inflators. Unwanted combustion products, including carbon monoxide, occur when potassium perchlorate is burned. The manufacture of the various gas generant chemicals should require no more than routine precautions. Besides the toxicity of the generants and products during normal deployment, other ABRS use considerations are exposure during theft, mounting add-on equipment, or replacement after crash. Concerning salvage operations, it appears that the ABRS would be left alone or deliberately deployed rather than removed. Of the disposal options (baling, shredding, and large-scale furnace melting), shreadding appears to present the greatest potential hazard.

FUEL HOSE PERMEATION: AN EMISSIONS PROBLEM?

New fuel hose material with improved resistance to degradation, volume increase, and permeation by aliphatic/aromatic fuels will be required as regulations decrease the amount of allowable hydrocarbon (HC) and fuel compositions change. Immersion tests were conducted to study the effects of temperature, hydroperoxide (formed by reaction of HC fuels with oxygen, "souring" of gasoline), and catalyst concentration on physical properties of such current fuel hose construction materials as fluorocarbons, epichlorohydrin (ECO), and nitrile (NBR). Permeation tests were conducted on these hose materials using fluid A which represented the maximum anticipated aromatic content of current and future automotive fuels, and fluid B which was representative of the current unleaded aromatic fuels. During immersion testing, a bisphenol-cured fluoropolymer and a diamine-cured fluoropolymer showed excellent resistence to "sour" gasoline. In permeation testing, thin diaphragms of Viton GH fluorocarbon elastomer (FKM-1) had low permeation rates in fluid A, which decreased with increasing elastomer thickness. Still lower permeation rates were found for fluid B. ECO underwent reversion during immersion testing in "sour" gasoline. Diaphragms of Hydrin 100 (ECO-1) had good resistance to permeation in fluid A; after 21 days, samples had a weight loss equal to about 19% of total fuel, compared to 40% fuel loss for the best NBR compound tested and 22% and 25%

for Hydrin 200 copolymer (ECO-2) and Hydrin 400 copolymer (ECO-3), respectively. Fluid B permeation rates were considerably lower in comparison. NBR underwent additional vulcanization in immersion in "sour" gasoline. Diaphragms of NBR-1 (Chemgum HR-765 with sulfur cure) had high permeation rates in fluid A, with NBR-2 (Chemgum HR-765 with perioxide cure) having higher rates. Permeation characteristics for fluid B were similar. Overall, equilibrium permeation rate was far lower for FKM-1

RUN-FLAT TIRE USES DOUBLE BEAD, REINFORCED SIDEWALL

An N-type, run-flat tire has been developed at Nissan Motor Co. Ltd. (Japan) which is used on a conventional wheel and has a simple structure with reinforced side walls and additional beads to fit rim flanges. It requires a conventional air valve and can be mounted with standard tire changers. Although the tire weighs 26% more than a conventional tire, the wheel assembly weighs only 15% more. About 6 kg can be saved per vehicle because the spare tire is unnecessary The N-type, run-flat tire meets all requirements for the Japanese Automobile Tire Manufacturers Assoc. standards for high-speed performance and load endurance. Bench tests and vehicle testing were conducted for run-flat endurance and characteristics, cornering stiffness, steering and stability, frequency response, transient response, steerings wheel effort, riding effort, and fuel consumption. The tires provide vehicle stability and mobility after tire deflation. During field testing of 15 vehicles over a total distance of 600,000 km, some punctures occurred. After running for 20 km to 120 km (average 65 km), the deflated tires were found to be normal and repairable.

TRAFFIC ON UTAH HIGHWAYS 1978

Average daily traffic volumes are tabulated on road sections of varying lengths in Utah during 1978 (and 1977 for comparsion); color-coded information is provided for the state highway system, Federal-aid urban local highways, Federal-aid secondary local highways, and Federal-aid primary highways not on the state system. A manual vehicle classification summary indicates the percentages of types of vehicles (Utah passenger vehicles, out-of-state passenger vehicles, light trucks, heavy trucks) using the various highway systems. Another tabulations depicts the following traffic data from all permanently located traffic counting machines: average traffic by day of week each month, average weekday traffic by months, average day of week traffic by months, the average day percentage of the average weekday, the monthly daily average percentage of the yearly daily average, and percentage breakdown by vehicle types for the yearly average. Unbound traffic volume maps are provided in an attached pocket.

RECENT TRENDS IN TRAFFIC INJURY

A series of graphs is presented and discussed which show the changes in the nature of injuries sustained in road accidents in Great Britain over the period 1958-1975. The Register-General's Satistical Reviews of England and Wales, in which tables are based on death certificates for 1958-1975, and the Annual Report of the Hospital In-Patient Enquiry for 1964-1973, were examined. Causes of death, primary injury for hospital inpatients, and average length of hospital stay were analyzed. It seems that an increasing proportion of deaths are being ascribed to internal injuries and a decreasing proportion to skull fractures. A considerable year-to-year variation in the average length of hospital stay was noted, but no long-term trends were detected. An annotation by J. p. Bull comments on the possible relationship of increased use of helmets and seat belts, and improved clinical care, to the decreasing proportion of deaths attributed to skull fractures. A second annotation by J.M. Potter questions the accuracy of "head injury" and "skull fracture" as a cause of death on forms used by the Registrar-General and Hospital In-Patient Enquiry.

FABRICATION OF AUTOMOTIVE BODY COMPONENTS IN GRFRP [GRAPHITE FIBER REINFORCED PLASTIC]

Procedures are described which were used by the Vought Corp. to fabricate automotive body components in graphite fiber reinforced plastic (GrFRP) for the Graphite 1979 Ford LTD. The effort was a joint venture with Milford Fabricating Co. (a subsidiary of the Budd Co.). Master tooling aid development, high-temperature epoxy molds, and component fabrication are discussed. During an eight-month period, 30 high-temperature epoxy bond-molds and 30 graphite reinforced plastic, car body components, of a highly complex configuration, were successfully fabricated. Aerospace technology and experience made a major contribution to the auto industry in this project to utilize GrFRP to reduce vehicle weight for improved fuel economy.

SHORT-TERM PHASE STABILITY OF AUDIO SIGNALS IN MOBILE RADIO VEHICLE-BASE LINKS

The phase perturbation of an audio tone transmitted over conventional frequency-modulated mobile radio links at frequencies of 72MHZ, and 462 MHZ was investigated. Data are presented from stationary and moving vehicles in a variety of urban routes and in mountainous terrain. The effects of noise and multipath propagation are identified. Results are interpreted in light of the requirements of a particular automatic vehicle monitoring system, which is briefly described. Results indicate that, as far as the vehicle-base link is concerned, a vehicle-location system of the type described is a perfectly practical proposition. Analyses show that, even when a speech signal is only just receivable, 90% of the readings will be in error by 20 to 40 degrees, equivalent to line-of-position errors of the order of 100 m. The contribution of the radio link will generally be much less than this. In urban areas where multipath range differences are usually quite short, the phase spikes can result in very large phase errors (of relatively low probability). A location or communications system sensitive to these must contain means of detecting phase perturbations and rejecting the associated data. More severe multipath effects can occur in hilly or mountainous areas where the path differences are longer. Although, in general, the peak errors are no greater than those in the city, the overall satistics are worse because of the greater rate of occurrence and longer durations of the perturbations.

FOUR DIESEL CARS: MERCEDES-BENZ 300D, CADILLAC ELDORADO, PEUGEOT 504, OLDSMOBILE CUTLASS

The pros and cons of diesel engines in general are discussed in terms of fuel efficiency, fuel availability, price, starting, acceleration, maintenance, durability and availability. The Mercedes-Benz 300D, Cadillac Eldorado, Peugeot 504, and Oldsmobile Cutlass diesel models are rated in terms of engine and drive-train, front and rear accommodations, interior noise level, ride, normal handling, accident-avoidance ability, brakes, safety features, bumper protection, controls and displays, climate control, predicted repair incidence, periodic servicing, and miscellany. The advantages and disadvantages of each model are noted. A progress report on long-term durability testing of a 1977 Volkswagen Rabbit diesel and a 1978 Oldsmobile Delta 88 diesel is provided. Among the recommendations presented are the selection of the Mercedes-Benz 300D as the diesel of choice if money were no object (the price tag is $21,000), and the VW Rabbit as the best buy. The Rabbit delivers the best fuel mileage of any car available and has a price tag of between $5500 and $6000 (some dealers demand more).

25 ANTI-THEFT IDEAS [AUTOMOBILE PROTECTION]

Suggestions for the car owner to prevent theft of his vehicle (99% of thefts are preventable according to police auto-theft investigators) are provided under two categories: procedures and devices. Among the procedures it is recommended to roll up the windows, lock doors, and remove keys; to keep spare keys in wallet or purse; to have different keys for ignition, doors, and trunk (giving parking attendant only the ignition key); locking in the glovebox the vehicle registration and papers showing the owner's address; taking claim checks when leaving desirable items in plan view inside a car. Suggestions for parking so as to discourage vehicle theft include parking only in a driveway with engine facing the street or in a locked garage, and avoiding dark parking places. Antitheft devices are described by type and function; they include anti-entry devices (door locks, external and internal hood locks), disabling devices (fuel shutoff, battery disconnect, brake system lock, pedal clamp, steering wheel bar, steering column band), and alarm systems (switch alarm, electrical drain alarm, motion detector alarm, pocket-pager-type alarm, coded start systems, garage alarm). Another antitheft system is the sandblasting of a code number into every piece of glass in the car, with the code kept in a cental file accessible to police departments across the country on a 24-hour basis. In order to avoid a "purchase theft", it is advised not to let prospective buyer take car for a test drive by himself, and not to accept checks of any kind. As a purchaser, one should not buy a car that does not have correct paperwork, and one should compare the vehicle identification number with the number on the registration.

ENOUGH OF YAWNING EXAMINERS AND PARALLEL PARKING [DRIVER LICENSING TEST]

various opinions about, and approaches to, driver licensing tests are discussed. The National Hwy. Traffic Safety Adminstration's (NHTSA) concern is to develop goals and research to improve the quality of driving and to suggest programs for the individual states to implement. Within NHTSA, there are those who feel that a driving test should be a severe test of the ability to control a vehicle, along with testing for observational ability and threat perception; others feel that the test should merely be a regulatory device and that post-licensing control is appropriate. A California driving instructor and former member of NHTSA'S Council on Advanced Driving advocates a tough licensing law, with far more emphasis on car control in driver's education courses. The chief of the Office of Traffic Safety in California believes an ability to work with vehicle dynamics should be required for a license; he also agrees with NHTSA that the major safety steps have already been taken, and that lowering the accident rate still further will require new driving attitudes on everyone's part. Since 1956, the British have been administering the Inst. of Advanced Motorists (IAM) hour and a half, 35-mile driving test (criteria listed in separate box) which demands rigorous standards of control, observation, and driving knowledge. Almost 150,000 persons have been admitted to IAM membership by passing the test, and their violation conviction rate is five times lower than that of the general public, and their accident rate 25% lower. It is estimated that if there were full implementation of this test (the test not nearly as available as the government test), that $200 million a year in accident damage could be saved. U.S. safety officials feel that a private, nonprofit organization such as IAM offers the most hope in affecting the licensing picture in America and that reduced insurance rates, as associated with IAM membership, is the best way to interest the general public in safer driving.

ANALYSIS OF PEDESTRIAN CROSSWALK SAFETY ON ONE-WAY STREET NETWORKS. FINAL REPORT

An exploration was made of causal factors that explain why left-turn-vehicle pedestrian accidents are twice as frequent as right-turn accidents on one-way street networks; the New York City Police Dept. accident file was used in the analysis. Driver visual field and attention are indicated to be primary contributory factors in left-turning accidents. Lighting and signal placement are also factors that explain some of the differences between left- and right-turning pedestrian accidents. Recommended countermeasures include extensive driver education to improve awareness of hazardous left-turning maneuvers, redesign of vehicle to improve sight angles (optimum design being equal left- and right-turning sight angles, elimination of vent-window design and increased windshield wiper area); placement of additional traffic signal above the turning crosswalk at the far side of the interesection in order to improve driver's target detection and to increase eye contact; and environmental changes (improved lighting, a clear sidewalk 50 ft upstream of intersection, a 12 ft to 15 ft parking lane, and a 3 ft indentation (into the block) of the turning crosswalk).

A LIMITED EVALUATION OF REFLECTIVE AND NON-REFLECTIVE BACKGROUND FOR OVERHEAD SIGNS. FINAL REPORT

A study was undertaken to evaluate the feasibility of using reflective sign sheeting, either engineering grade (Class I) or high-intensity grade (Class II), as background material for selected overhead highway signs, or using presently accepted nonreflective, opaque, procelain enamel backgrounds but without external illumination. Two sets of overhead signs were placed at two sites, at the junction of I-81 I-78 east of Harrinsburg, Pa., where motorist interviews and photometric readings were recorded. The results indicate that the motorists generally preferred the unlighted high-intensity signs as compared to unlighted nonreflective or engineering grade signs. Photometric readings indicated greatest contrast ratio with reflective button copy on the nonreflective background when not illuminated. It is concluded that signs with the reflective backgrounds and legends used in this study could fully provide an acceptable level of service when not self-illuminated on freeway-type highways with tangent section a minimum of 1200 ft in lenght. Illuminated, nonreflective signs with button copy yield high contrast ratios and provide a level of service equal to the alternate sign types tested. The individual states should have the prerogative of deciding which background type; legend, and illumination condition provide the best service in their areas of jurisdiction.

AN ALTERNATIVE TO THE CRIMINALITY OF DRIVING WHILE INTOXICATED

The following negative aspects of conventional DWI (driving while intoxicated) enforcement programs are outlined: failure to change the behavioral attitude of the offender, lack of wholehearted support of the police, tendency to be unjust, corrupt, and self-defeating, and placement of defense counsel in a nonproductive and unsatisfying role. The following criteria are outlined for a successful DWI enforcement program: a substatial increase in arrests of offenders; a rapid, low-cost flow of apprehended drivers through the courts; a concerted, meaningful effort from many sources towards changing the behavior of the arrested offender; a finality to litigation and a probationary period to determine the effectiveness of the treatment program; an ongoing evaluation of the overall effectiveness of the program; and a balance of involved economic interests. In the three-year Park Forrest, Illionis, Lutheran General Hosp. Program for DWI offenders, a two-page information sheet is given to the offender, emphasizing the seriousness of the offense and defining possible sanctions if the offender proceeds to trial and pleads guilty or is found guilty. An alternative is offered to the offender to participate in a voluntary alcohol diagnostic evaluation test and recommended treatment program tailored to offender needs. The hospital evaluation program provides a psychosocial evaluation of drinking/drug impact on a person's functioning. Upon completion of testing procedures, the therapist outlines for the prosecutor his findings and recommendations. Copies of the report are given to the defendant, defense counsel, and arresting officer. In a petition, the parties ask the court to accept a guilty plea, record a finding thereof, set a temporary $100 fine and $5 costs, and honor a joint motion to vacate that finding and penalty after a one-year probationary period. The fine and costs are paid only if the motion to vacate is denied. The arrrest rate has been around 200 to 350 DWI cases annually for the Park Forest community of 34,000 with a recidivism rate around 3%. There have been no jury trial and only a few contested cases.

HELMET LAWS DWINDLE: DEATH TOLL MOUNT [MOTORCYCLING]

Various statistics and opinions are cited concerning helmet usage by motorcyclists, with emphasis on mandatory helmet use laws. Information is provided on motorcycle helmet safety, standards, construction, and proper use. Although a 1974 National Hwy. Traffic Safety Administration (NHTSA) study found that nonhelmeted cyclists suffer three times as many fatal or serious head injuries as helmeted cyclists motorcyclists have apparently convinced Congress and most state legislators that government should not mandate helmet usage. A 1967 NHTSA rule withheld Federal highway funds from states not requiring helmet usage; by 1975, 47 states, the District of Columbia, and Puerto Rico had mandatory helmet laws. A 1976 law prevented NHTSA from enforcing helmet laws by withholding funds. At present, 29 states do not require motorcyclists 18 years or older to wear helmets. Motorcycle fatalities rose 24% in 1977 over 1976, although registration rose only1%. The motorcycle industry and motorcyclist groups have lobbied strongly on the Federal and state levels against mandatory helmet usage, with the right of personal choice proving to be the strongest argument. On the other hand, insurance companies, medical experts, and a Federal judge contend that society pays the bill when a helmetless cyclist is severely or fatally injured. Many physicians support helmet use legislation not only on the basis of medical research findings but also because of personal experience in emergency rooms. An American Medical Assoc. report compiling research by experts on both sides of the issue counters charges that helmets contribute to neck and spine injuries and cause accidents. Although the general consensus is that helmets increase the chances of surviving a motorcycle accident, motorcyclists are not pleased with the government's approach to motorcycle safety. Meanwhile, Federal and state regulators predict that helmet use laws may return when motorcycle fatality figures are made available.

BRAKING AND LOCKING CHARACTERISTICS OF VARIOUS TYPES OF MOTORCYCLE BRAKE SYSTEMS (BREMS- UND BLOCKIERVERHALTEN VON MOTORRADERN MIT VERSCHIEDENEN BREMSSYSTEMEN)

The braking and wheel-locking characteristics are examined of the conventional motorcycle brake system (separate actuation of the front and rear brakes) and the possibilities and problems associated with a new system being developed (simultaneous actuation of the front and rear brakes). Although the conventional system allows the experienced driver to achieve an optimal deceleration, the inexperienced motorcycle driver, accustomed to driving cars, fails to achieve the proper decelerations for a given road traction conditions. By locking a rear or front wheel too early, the novice motorcyclist initiates a fall which could have been avoided. The "combined" brake system with coupled rear and front brake actuation could help to prevent this type of fall. A detailed analysis indicates that it is difficult to design brake systems and pressure equalizers which would be satisfactory under all load and road conditions and which would always compensate for lack of rider skill.

SELECTING THE OPTIMUM ENGINE CONNECTING ROD MANUFACTURING PROCESS

Automotive engine connecting rods are used as an example in applying an optimum manufacturing process selection algorithm. The technique used to compare manufacturing processes, a modification of Kepner-Tregoe Problem Analysis, involves the itemization of basic goals into small entities, settings of priorities on these goals, and summing the effect of how well each process option satisfies each specific goal. Prior to defining the goals or "wants", mandatory processing requirements or "musts" are determined. These "musts" (e.g. use available material, yield an acceptable part) are essential elements which serve as go/no go decisional criteria. Five processing scenarios (forging by gas slot heat and hammer forge, or by induction heat and press forge, nodular iron casting, hot formed powder metal, and precision warm forming) are compared in terms of the following goals: use of available material, minimization of energy use, reduction of vehicle weight, minimization of piece cost, high quality, minimization of investment, use of existing technology, viable steps to production, and positive safety, environmental, and personnel effects. Casting is determined to be the optimum connecting rod manufacturing process, based on the assumptions that a new product is involved and that a building is available without equipment or personnel.

HIGHWAY ACCIDENT REPORT. OVERTURN OF A YPSILANTI, MICHIGAN, BOYS CLUB BUS, I-75, NEAR TIFTON, GEORGIA, APRIL 11, 1978

A "school bus"-type bus operated by the Ypsilanti (michigan) Boys Club, occupied by 56 boys and 2 adults, was southbound on I-75 near Tifton, Georgia, en route to Disney World, Florida. As the bus exited I-75 at a safety rest area, it went off the road while negotiating a right curve on the exit lane, overturned, and struck a tree. Three passengers were killed, and the driver and 25 passengers were injured. The probable cause of the accident was the driver's loss of directional control of the bus on the curve because of excessive speed due to the failure of the accelerator return spring, which resulted from improper maintenance. Contributing to the accident were severely underinflated tires, deteriorated suspension, excessive luggage on the roof, and driver fatigue. Since the accident bus did not transport pupils to school, it did not satisfy the requirements of the Michigan School Code of 1976 and did not have to be inspected. Although the weakened, fatigued accelerator return spring would probably not have been discovered through a periodic state-required vehicle inspection, a properly designed vehicle maintenance program should have identified the defect, resulting in its replacement.

HIGHWAY ACCIDENT REPORT. OSTERKAMP TRUCKING, INC., TRUCK/FULL TRAILER AND DODGE VAN COLLISION, U.S. 91, NEAR SCIPIO, UTAH, AUGUST 26, 1977

A 1973 Dodge Van and a 1977 Peterbilt truck, pulling an empty 1977 Reliance full trailer, collided head-on during a moderate-to-heavy rainstorm on U.S. 91, 8 mi north of Scipio, Utah. The eight occupants of the van were killed, and the truck driver was injured. The truck driver said that when the vehicles were quite close and he believed the van driver was not returining to his side of the road, he thought that he must reduce speed to give the van driver time to straighten out. He said that after rapidly and firmly applying the brakes on both truck and trailer, the combination begin to skid. As he was attempting to steer out of the skid, he said that he attempted to engage the "jake brake", a device which increases the engine's braking capability but is intended for energy absorption during downhill operations. The physical evidence indicated that both vehicles were straddling the centerline at impact; the truck/full trailer was almost fully on the van's side of the road, while the van was just across the centerline. This evidence did not provide enough information to determine the movements of either vehicle before impact. Limits in this evidence and research data prevented confirmation or denial that the truck driver's alleged evasive actions were necessary, that they took place, or that they would have produced his described loss of control. During the evaluation, a significant lack of research data on the performance of lightly loaded truck tires, and the potential effect of varying pavement frictional quality was noted. The southbound pavement surface approaching the accident site was found to have a progressively lower and widely fluctuating wet frictional quality and an average wet frictional quality below recommended values. Standard pavement inventory test procedures would not have detected these pavement problems at the accident site. the probable cause of this accident was either or both drivers failed to maintain their vehicle in the proper traffic lane for undetermined reasons.

DIESELS AND FOUR-WHEEL DRIVE

Among the most technically interesting exhibits at the 1979 Geneva Motor Show were several new diesel engines and four-wheel-drive vehicles. Peugeot has produced a turbocharged version of its 2.3 L diesel for the 603, with increased maximum output (51 KW to 59 KW), increased maximum power (4150 rpm vs. 4500 rpm), and maximum torque of 184 Nm at 2000 rpm (an increase of 40%). Peugeot's diesel for the 305 is a new unit based on the 1.45 L gasoline unit fitted to that car; maximum power and torque, respectively, are 36 KW at 5000 rpm and 87Nm at 2500 rpm. Two other new diesels from VW include the five-cylinder unit, now available in the Audi 100, and the six-cylinder unit in the Volvo 244 GL; specific outputs, respectively, are 51 KW and 60 KW at 4800 rpm, with maximum torques of 123 Nm at 3000 rpm and 140 Nm at 2800 rpm. Detail changes have been made to the diesels in the Mercedes-Benz 200D and 240D models, with outputs for the former increased from 40 KW to 44 KW, and for the latter from 48 KW to 53 KW. Volvo has enlarged its 2.1 L gasoline engine to 2.3 L for the 242 GT model, with a maximum power output of 103 KW at 5750 rpm, and maximum torque of 191 Nm at 4500 rpm. Saab's experimental car is intended to show the potential for turbocharging; the car develops 128 KW at 5500 rpm and 295 Nm at 3500 rpm. GM'S new 1.3 L engine features the crossflow aluminum cylinder head; this engine has an output of 44 KW at 5800 rpm and maximum torque of 97 Nm at 3200 rpm. The Land-Rover V8 engine has been revised to give more low-speed pulling power (maximum output limited to 68 KW at 3500 rpm, although maximum engine speed is 5000 rpm), and has a maximum torque of 225 Nm at 2000 rpm. Two new versions of the Chrysler Sunbeam are the Sunbeam lotus, which is powered by a 2.2 L version of the Lotus 16-valve engine, and the Ti, powered by a version of the Chrysler 1.6 L unit. The most significant of the four-wheel-drive vehicles are the Mercedes-Benz G Range and the VW Iltis.

THE POTENTIAL FOR ACTIVE SUSPENSION SYSTEMS

The two fundamental deficiencies in the conventional approaches to suspension system design are the limiting performance characteristics of traditional passive element suspensions, and the limiting mathematical procedures used in the design of both passive and active suspensions. Since active suspensions offer considerable potential for overcoming the limitations of passive suspensions,the most appropriate method for designing them must be determined. The synthetic approach to the design of active suspensions has distinct advantages over the analytical procedures of conventional design methods, which involve analyzing the behavior of predefined suspension configurations, a process which requires considerable time and effort. The synthetic approach enables the desired dynamic characteristics to be assigned before the suspension is constructed and determines the most suitable suspension configuration. The synthesis of suspensions using modern control theories (optimal control theory, modal control theory) is a powerful design technique for both active and passive suspensions.

EMERGENCY VEHICLE OPERATIONS COURSE

An Emergency Vehicle Operations Course (EVOC) was conducted throughout North Carolina by the Center for Safety and Driver Education at Appalachian State Univ., Boone, N.C. and the Safety Center at East Carolina Univ. The classroom session included two films: one called "Code Three," depicting a police officer on an emergency run to an accident scene, the other entitled "Six Deadly Skids," dealing with six different types of skids and the effect of each on the driver and vehicle. A slide presentation was used to describe each of the in-car activities and to aid in the discussion of physical and man-made laws. Students received a notebook (with various pamphlets includ-

ed). The main driving exercises, developed by Vehicle Dynamics Lab., involved skid control (braking, cornering, and power skids), serpentine course, evasive maneuvers, controlled braking, off-road recovery, and double-lane change. Each exercise was first presented in regular passenger sedans, then in both a van and a modular ambulance.

INSTITUTE URGES ACTION FOR CHILD PROTECTION [INSURANCE INSTITUTE FOR HIGHWAY SAFETY, CHILD, RESTRAINTS]

Dr. William Haddon, Jr., of the Insurance Inst. for Hwy. Safety (IIHS), spoke before the House Commerce Subcommittee on Oversight and Investigation, on child protection in passenger cars and vans. His address is summarized, with still photographs from the film sequences presented at the hearing. Filmed (slow motion) results of new IIHS crash tests using tests dummies and popular 1979 model vehicles showed the following situations: an unbelted mother crushing her lap-held baby violently into the car's instrument panel and windshield in a frontal crash of less than 25 mph; unrestrained children ejected from the open rear window of a station wagon in a 30 mph collision; two youngsters, unrestrained, being violently thrown about in a van crash of less than 25 mph; and an unrestrained infant, lying on the front seat, hurled forward in a 25 mph crash to collide with the long-known child impact area of the instrument panel. Other sequences of the film, showed how well even small children were protected in crashes when wearing adult safety belts. To reduce the toll of nearly 2000 children killed and thousands seriously injured annually in auto crashes, Haddon stated that action must be taken by state and local governments who can mandate child protection laws, the National Hwy. Traffic Safety Administration (NHTSA) which should amend its present Federal Motor Vehicle Safety Standards (FMVSS) in order to eliminate hostile vehicle interior structures, auto manufacturers who can properly design and build cars for occupant protection, and parents and other adults who can place children in restraints. NHTSA administrator Joan Claybrook told of agency efforts to require dynamic testing for child restraints and a current series of child restraint workshops, and Robert E. Vanderbeek, of the League Insurance Companies of Southfield, Mich., described his company's upcoming program for supplying child restraints free of charge to policyholders. In separate sections, it is noted that Joan Claybrook will push for revision of FMVSS 201, Occupant Crash Protection From Interior Impact, and Dr. Haddon calls for proper packaging of human cargo.

VACATION PLANNER [CAR PREPARATION, TRAVEL PLANNING, AND DRIVING TIPS]

Information is presented for the vacationing motorist on preparing his car for its journey, planning the trip, saving gas, keeping the children occupied, and staying awake. Vehicle preparation tips include inspection of the tires, belts hoses, oil, filters, steering system, transmission, suspension, exhaust system, electrical system, and brakes. Items to carry for on-the-repairs include spare tire and jack, assortment of tools, oil, some replacement parts, jumper cables, flashlight, flares, and first-aid kit. Travel planning suggestions include knowing exactly where you want to go, how far you can go on a tankful, where you want to be each night, mapping out the route getting the assistance of a local auto club, and calling ahead for reservations. Essential items not to be forgotten include driver's license, registration, proof of insurance, leave papers, checks and credit cards. To save gas, comfort, and for passenger comfort the car should not be overloaded. Travellers should be stingy about space, take along only minimal clothing, and distribute passengers (each to have a safety belt) and luggage evenly. Advice for entertaining the kids includes giving them coloring books and reading materials, assigning them tasks that require road watching, playing quiz games and singing, and stopping about every two hours for a break. Gas-saving tips include driving slower, at a constant speed (e.g. 50 mph), not accelerating or decelerating rapidly, minimizing use of air conditioning, avoiding unnecessary stops, having the car properly tuned, and having the tires properly inflated. Suggestions for staying alert include finding things to break the monotony, such as switching drivers, talking, playing word games and listening to the radio, and stopping for a break every few hours.

TESTING DOUBLES TRAILERS AT THE THRESHOLD OF ROLLOVER [TRACTORS PULLING TWO TRAILERS]

Tests of maneuverability at the rollover limit were made at the Univ. of Michigan's Hwy. Safety Res. Inst. on a full scale tractor/double trailer loaded to simulate a full gasoline load and equipped with outriggers to prevent overturn. The power unit was a short-wheelbase, 3-axle GMC cab-over-engine highway tractor; the lead semitrailer was a 9300-gal capacity Fruehauf tri-axle, 12' 8" high, with three internal compartments; the following trailer was a Fruehauf 7700-gal capacity tri-axle, 13' 3" high, utilizing a tandem-axel converter dolly. Overall combination length was 55 ft, and gross vehicle weight was 152,000 lb. In a simulated lane change as an emergency maneuver, it was found that the steering maneuver amplified at the converter dolly, and that the oscillation continued after the tractor had straightened out. Tests of a dolly hitch modification (a 4-point hitch making the dolly rigid in yaw and roll, but allowing verical and pitch movements) proved that this modification upgrades the full trailer roll stability to that exhibited by the lead trailer hitched to the tractor. The modified double has slightly less maneuverability than when using the 3-point, pintle-hook hitch, but is still more maneuverable than the long-wheelbase, single-trailer rigs. The tests also proved that the unmodified "A" train is unstable in yaw oscillation if only the rear compartment is loaded and speeds exceed 50 mph. In other testing, a total of 22 retaining bolts were added to the spring suspensions to reduce the lash space to 1/4" to 3/4". This minor modification resulted in a 15% improvement in roll stability. A third modification, lengthening of the wheelbase, offered little benefit to stability. It was concluded that, when modified with a 4-point hitch, the Michigan double-bottom tanker train may have better safety and fire hazard exposure than either the long semitrailer or the short Michigan single that was legislated.

HS-026 338

NEW HITCH HARDWARE LEGISLATED TO REDUCE DOUBLES ROLL, JACKKNIFE [TRANSPORT OF FLAMMABLE LIQUIDS IN DOUBLE TANK TRAILERS]

two stabilizing devices have so far been certified by the Michigan State Police for the following trailer in a double trailer transporting flammable liquids. Certification requires that a device provide antiroll support from the lead trailer, and prevent the full trailer from pivoting freely about the kingpin of the converter dolly (i.e. prevent jackkniffe). One device in the Fruehauf 4-point hitch, a very short link pinned to the rear of the lead trailer and to the front of the converter dolly of the following trailer. It locks out yaw and roll completely, allowing only vertical and pitch movements. With this device, the converter dolly no longer steers separately, but is positioned directly behing the wheels of the lead trailer. The other device is the Telescopic Steering Stabilizer patented by Truck Safety Systems, Inc. (Tecumseh, Mich.). This device is added above the regular tongue and hitch of the converter dolly; it locks out the roll of the following trailer and limits the trailer swing. It is connected directly to the rear of the lead trailer frame and the front of the following trailer frame. By 1981, gasoline will not be permitted in double-bottom trailers in Michigan; only the lead trailer will be allowed to haul gasoline. Since No. 1 and No. 2 fuel oils have a flash point above 70 degree (unlike gasoline) they may be transported in double-bottom trailers now and beyond 1981, if the train is equipped with a certified stabilizing device. Three papers concerning double trailer stability are cited: SAE-781064, SAE-781065, and SAE-781066.

CLASSIFICATION OF MEN ARRESTED FOR DRIVING WHILE INTOXICATED, AND TREATMENT IMPLICATIONS. A CLUSTER-ANALYTIC STUDY

The study attempts to identify by cluster analysis the patterns of alcohol impairment and neuroticism in a sample of men arrested for driving while intoxicated (DWI) in philadelphia, and to differentiate types of offenders according to psychosocial characteristics and drinking histories, suggesting how distinct types of DWI offenders might be treated in the present judicial, educational and clinical framework. Statistical analysis of blood alcohol concerntration at time of arrest, quantity-frequency level of drinking and scores on an impairment index and the N Scale of the Eysenck Personality Inventory differentiated seven types among 1500 men arrested for driving while intoxicated. Treatment regimens for the seven groups are suggested.

TRAFFIC FLOW EVALUATION OF PAVEMENT INSET LIGHTS FOR USE DURING FOG. FINAL REPORT

A lighting system consisting of pavement inset lights to aid motorists during periods of fog was installed on a 5.8-mile (9.4-km) section of I-64, traversing the top of Afton Mountain. Data were collected before and after the lights were installed. Traffic flow parameters were vehicle speeds headways, queues, and lateral placement, and a before and after accident analysis was made. Overall the lighting system led to higher nighttime speeds, an increase in speed differentials for various cases during both day and night, and a decrease in nighttime headways and queuing. Although such changes in traffic flow characteristics might lead to an increase in the potential for accidents, they are considered to be a result of the inset lighting system providing improved delineation for the guidance of motorists, and a system of matrix type fog warning and advisory speed signs is proposed for regulating speeds within the system of guidance lights.

AUTOMOBILE FUEL ECONOMY STANDARDS FOR 1981-1985. A REVIEW AND RECOMMENDATIONS

The Dept. of Commerce (DOC), after analyzing the fuel economy standards proposed by the Dept. of Transportation (DOT), concludes that the goal of 27.5 mpg by 1935 is feasible, but prefers an alternative method of implementation. DOT proposes "front-loaded" standards: more rapid increases in mpg required during the early years of the program than in later years; the DOC recommends a straight-line approach requiring equal annual mpg improvements. Reasons for this preference include cost effectiveness of the straight-line approach as opposed to the cost of the front-load standard, an adequate margin for error in view of the technological and economic uncertainties involved; the increased regulatory burden faced by the auto industry through the mid-1980's in complying with more stringent emission and safety regulations and fuel economy standards, for which the straight-line approach would provided more flexibility. Savings to the auto buying public by switching from the front-loaded to a straight-line standard are estimated to be approximately $2 billion, in 1978 dollars.

MOTORISTS' REQUIREMENTS FOR ACTIVE GRADE CROSSING WARNING DEVICES. FINAL REPORT

A two-year study examined some of the basic problems involved in improving the design of active warning devices intended to make motorists more aware of grade crossing hazards. Emphasis was placed on the improvement of the attention-getting aspect (conspicuity) of active crossing warning devices which was presumed to correlate positively with improvements in grade crossing safety. Following a literature survey, an indoor laboratory test was conducted in the Federal Aviation Administration Low Visibility Res. Facility. More than 150 subjects gave over 20,000 responses to flashing light displays. Results were anlayzed to determine effects of color, flash rate, brightness, size, and placement under daylight, darkness, and daytime fog conditions. The laboratory tests resulted in development of two improved devices which were field tests on actual grade crossings. The first device consisted of an array of three eight-inch, white (clear) strobe lights added to a standard flashing warning system at a high accident rate urban crossing in Richmon, Calif. The second device was added to a gate arm and consisted of three small strobes, colored red, white (clear), and blue, installed at a rural highway grade crossing with high-speed truck and automobile traffic. Due to project restraints, no long-term safety improvement analysis could be conducted. Because there was no evidence of driver confusion during the conduct of these field tests, it is concluded that colored lights other than red can be used in moderation as add-on to existing active cross warning devices to increase conspicuity. The high composite (not from a single source) flash-rate devices that were installed did not result in any erratic driving behavior of approaching motorists. (Appended are an annotated bibliography (divided into subject categories) and discussions of visual perception, statistical procedures, and raw data (procedures) results (including tabulated summary).

THE EFFECTS OF RADIO AND PRESS PUBLICITY ON THE SAFE CARRIAGE OF CHILDREN IN CARS

In Apr 1978, Australia's Office of Road Safety conducted a national press and radio publicity campaign aimed at increasing the fitting and use by children of conventional seat belts where child restraints were not available, and relocating children, particularly those unrestrained, from front to rear seats. Undertaken in states with and without child restraint legislation, the effect of the campaign was evaluated using data from roadside observations of restraint fitting and use. Although the campaign was not effective in achieving the desired changes, it did provide valuable data on the transport of children in cars. It was found that over one-third of children have no form of restraint available in the seating position they occupy; only one-fifth to one-quarter of children have a child restraint available, and about one-quarter of these are unapproved. The usage rate is between one-quarter and one-third of all children; about half of the children with an available restraint use it; where child restraints are fitted, usage rate is high (about 90%). The majority of children ride in the rear seat, with 10% to 15% riding in the front seat in Victoria, where unrestrained children are prohibited in the front seat, and around 25% to 30% in South Australia and Western Australia where there is no such prohibition. A copy of the safety campaign press advertisement is appended.

TRANSPORTATION FOR THE ELDERLY AND HANDICAPPED: PROGRAMS AND PROBLEMS

A distillation of papers on transportation for the elderly and handicapped includes presentations from a national perspective, a brief history of the major Federal legislation affecting transportation programs for elderly and handicapped persons, one desabled individual's opinion on barrier-free transportation, discussions of planning and implementation methods, examples of state (California, Oregon, Pennsylvania, Georgia, Tennessee), rural (Iowa, South Carolina), and urban (Louisville, Atlanta, Montgomery, Dade County (Fla.), Evanston (Ill.), San Antonio, Spokane) programs, and discussion of driver training and equipment selection. The authors include staff representatives from both the House and Senate Committees on Aging; other Federal officials; advocates from the transit industry, the user groups, and the nonprofit social agencies; planners and consultants who have developed model methodologies; state and local program managers; and legal experts. A glossary is provided, defining possibly unfamiliar terms and abbreviations used by the authors, as well as a list of the authors and their addresses and phone numbers. This report is a companion to an annotated bibliography, "Transportation and the Elderly and Handicapped: A Literature Capsule" (Jan 1977).

SIMPLIFIED AIDS FOR TRANSPORTATION ANALYSIS. ANNOTATED BIBLIOGRAPHY OF ANALYTICAL AIDS. FINAL REPORT

In Jan 1976, the Dept. of Transportation issued Technical Notice DOTT-1-76 requesting transportation planners, engineers, and transit operators to submit useful but not widely known manual techniques that could be developed and distributed as simplified aids for transportation analysis. An annotated summary is presented of each of the more than 70 analytical aids that were submitted. For each case, a brief description of the aid is provided, the submitting person or agency is identified, and, in many cases, a reference document is suggested which describes the technique and/or its application. The descriptions are intended to assist the transportation analyst in determining which of the aids might be useful in a particular local application. The aids, presented alphabetically by source, are described in the following functional categories: planning, evaluation, and design for conventional bus and transit and paratransit; planning, evaluation, and design for express bus and rail transit; transit route monitoring and evaluation; sketch planning analysis; trip generation analysis; land use planning and activity allocation analysis; economic analysis; parking analysis; environmental analysis; and miscellaneous functions, such as traffic safety, traffic operations, intercity travel, and air travel.

SUMPLIFIED AIDS FOR TRANSPORTATION ANALYSIS. DERIVATION AND USE OF AUTOMOBILE AVAILABILITY AS A VARIABLE FOR ESTIMATING TRAVEL DEMAND. FINAL REPORT

As one of a collection of useful but not widely known manual techniques employed by local transportation planners, engineers, or transit operators, a method is described for deriving an important socioeconomic variable in travel demand estimation, namely, automobile availability per household. This variable was found to be a function of two other variables: the average market price of homes, and the percent of home ownership. Local data at the level of detail required for transportation demand analyses (e.g. transportation planning zone, traffic zone, or census block) is generally more readily available for these factors. The analytical aid, required data and information, application procedure, and analysis output are outlined in an introductory section. The results of a research project are presented which determined the functional relation used to estimate automobile availability per household, and a method is provided for developing a similar function using local data. Two examples of travel demand models (trip generation, model split) using the variable are presented. Shortcomings and limitations of the analytical aid are addressed.

SIMPLIFIED AIDS FOR TRANSPORTATION ANALYSIS. ESTIMATING ANNUAL RIDERSHIP AND OPERATING EXPENSE FOR FIXED ROUTE BUS SYSTEMS IN SMALL URBAN AREAS. FINAL REPORT

As one of a collection of useful but not widely known manual techniques employed by local transportation planners, engineers, or transit operators, a simple method is presented for estimating the annual ridership and operating expenses of fixed-route bus system alternatives in urban areas with populations of less than 300,000. The method is based on regression equations generated principally from 1974 operating data for 55 U.S. fixed-route bus systems. These equations can be used to develop preliminary estimates of the annual ridership and public financial operating assistance required for such systems in small, urban areas. The equations can be solved using a hand calculator and readily available data inputs. The analytical aid, required data and information, and analysis output are outlined in an introduction section. The estimation equations are described, and their use illustrated. Shortcomings and limitations of the analytical aid are addressed.

SIMPLIFIED AIDS FOR TRANSPORTATION ANALYSIS. METHODOLOGY FOR TRANSIT ROUTE EVALUATION. FINAL REPORT

As one of a collection of useful but not widely known manual techniques employed by local transportation planners, engineers, or transit operators, a method is presented for evaluating individual transit routes for a fixed-route, fixed-schedule urban transit system. Individual transit system routes are evaluated semiannually, based on a comparison of nine performance factors with established route standards set for each factor. These factors are average revenue passengers per month, average monthly passenger growth, percent growth per month, total passengers per trip, average capacity utilization factor, percent transfers, operating revenue per mile, operating revenue per hour, and net operating cost per passenger. Input data used in the evaluation are recorded semiannually and scores computed for each of the performance factors for each route according to an evaluation score algorithm. Scores are then added for each route, and routes ranked by their total evaluation score. Results are used as the basis for route refinement and modification decisions. The procedure is best applied to systems whose overall ridership is growing. The analytical aid, required input data, and application procedure are outlined in an introductory section. detailed instructions for conducting a transit route evaluation, and an example to illustrate the procedure and its output arte provided. Shortcomings and limitations of the analytical aid are addressed, including ways to modify it to suit individual user needs. Appended is a list of the analytical variables, including their definitions, notations, and derivations.

SIMPLIFIED AIDS FOR TRANSPORTATION ANALYSIS. METHODOLOGY FOR ESTIMATING PARKING ACCUMULATION. FINAL REPORT

As one of a collection of useful but not widely known manual techniques employed by local transportation planners, engineers, or transit operators, a method is presented for estimating the accumulation of parked vehicles within a study area on a typical weekday. Parking accumulation and utilization of parking facilities may be estimated for all parkers, long-term, and/or short-term, based on an estimate of daily automobile trip destinations, an inventory of available parking supply, and a set of parking "accumulation factors" (which may be derived from a parking survey within the study area or from default values which are provided). The primary use of the method is to analyze the adequacy of available parking supply in relation to expected parking demand. The method may also be used to monitor and suggest revisions to automobile travel impedance values used in transportation planning models. The analytical aid, required input data and information, application procedure, and analysis output are outlined in an introductory section. A detailed description of the data and information required and the most likely data sources are provided. The step-by-step procedures for calculating parking accumulation, determining the utilization of existing or planned parking facilities, and estimating the required new or additional parking spaces are described. The analysis procedure is illustrated with a hypothetical case study. Shortcomings and limitations of the analytical aid are addressed. Appended is a description of the derivation of the accumulation factors.

SIMPLIFIED AIDS FOR TRANSPORTATION ANALYSIS. ESTIMATING FRINGE PARKING SITE REQUIREMENTS. FINAL REPORT

As one of a collection of useful but not widely known manual techniques employed by local transportation planners, engineers, or transit operators, a method is presented for identifying candidate sites for change-of-mode fringe parking facilities, for estimating specific parking facility requirements at these candidate sites, and highway access requirements. The analytical aid, required data and information, and analysis output are outlined in an introductory section. criteria for use in identifying candidate change-of-mode sites are suggested, a qualitative analysis method is described, with input data required to perform preliminary screening of the sites and to select those sites which warrant further analysis. A five-step quantitative procedure is described for use in determining parking space requirements for candidate sites; the procedure involves delineating origin and destination market influence areas for each site and identifying the transportation zones which make up each influence area; estimating total daily person trip interchanges between origin and destination market influence areas; estimating the proportion of each trip interchange that will use the line-haul mode (commuter railroad, rapid transit, or express bus); estimating the proportion of daily line-haul riders that will use the change-of-mode fringe parking facility; and calculating the new or additional parking facilities required at each site. A method for estimating highway access requirements for candidate sites is provided, and a format for preparing an evaluation profile of the sites is presented. Shortcomings and limitations of the analytical aid are addressed.

TURBOCHARGERS AND TURBOCHARGED ENGINES

Following an overview of the automotive turbocharger, 12 papers are compiled on turbochargers and turbocharged engines. Papers on turbocharged engines cover the following topics: turbocharging small-displacement, spark ignition engines for improved fuel economy, installation and design problems associated with the automotive turbochanger turbocharging four-cycle diesel engines, turbocharger compressor performance evaluation and critical flow field measurements, and exhaust emissions from a European light-duty turbocharged diesel. Papers on "turbochargers in the 80's" cover the following topics: current trends and future prospects for turbochargers in the 1980's, variable-area turbocharger for high-output diesel engines; the effect of compressor and turbine specific speed on turbocharger efficiency and engine performance; centrifugal compressor development for a variable-area turbocharger; series turbocharging--a requirement for high specific output vehicular diesel engines; estimting the influence of pulsating flow conditions on the performance of a turbine; and Helmholtz-tuned induction system for turbocharged diesel engine.

TURBOCHARGING SMALL DISPLACEMENT SPARK IGNITION ENGINES FOR IMPROVED FUEL ECONOMY

An approach is described for improving fuel economy by using turbocharged, spark ignition engines of relatively small displacement, 1.6 L, 4-cylinder and 2.2 L, 5-cylinder, to replace larger, naturally aspirated engines of the same power potential. A low-flow turbocharger is used to realize a given peak performance with good power characteristics over the entire engine speed range. The boost pressure is controlled by a wastegate. The air-fuel mixture is prepared by a two-stage carburetor at the intake of the turbocharger compressor. The oxygen concentration in the exhaust gas is measured by an oxygen sensor upstream of a three-way catalyst. A detailed description is given of the turbocharger installation, charge pressure control, and air-fuel mixture control. A system for the stabilization of engine speed at idle with simultaneous increase of exhaust gas temperature is described. The effects of the compression ratio on fuel economy in the Urban Driving Cycle (UDC) are discussed. Preliminary emission and fuel economy test results are presented for the 4-cylinder engine. UDC emissions for the 3000-lb vehicle with 1.6 L engine were 0.19 g/mi HC (hydrocarbon), 3.27 g/mi CO (carbon monoxide), and 0.71 g/mi NOX (nitrogen oxides); Highway Driving Cycle (HDC) emissions were 0.01 g/mi, 0.91 g/mi, and 0.78 g/mi, respectively, for HC, CO, and NOX. Further work is needed in tuning the carburetor feedback system and in exhaust gas aftertreatment to meet emission goals. Fuel economy results were 43 mpg HDC and 26 mpg UDC.

INSTALLATION AND DESIGN PROBLEMS ASSOCIATED WITH THE AUTOMOTIVE TURBOCHARGER

The Schwitzer S6 automotive turbocharger was designed with the philosophy of severe economic guidelines and mounting versatility. In order to meet the design goals, a number of unique items had to be considered and incorporated in the turbocharger. The current design can be mounted from within 4 degree of horizontal to within 10 degree of vertical. The bearing housing is sandwiched between the compressor end flange plate and the turbine housing, with retention by three cross bolts located at 120 degree intervals. This arrangement allows the gravity oil drain to be rotated within the intervals between the bolts. The bearing system was simplified by using a free-floating, nonrotatable sleeve bearing with axial thrust capability to replace the Schwitzer rotating journal with a separate thrust bearing. The wastegate system is comprised of a rotary valve actuated by a remote boost-controlled, spring-loaded diaphragm. This concept allows the turbine to be bypassed to avoid any increase in engine back pressure as a result of the presence of the turbocharger at high cruising speeds. The rotary valve also has the advantage of a positive self-cleaning feature and requires less close tolerance machining than a more conventional pop-off valve arrangement. The control mechanism for the wastegate is located remote from the turbine housing, which allows the use of less expensive, less corrosion-resistant parts.

TURBOCHARGING FOUR-CYCLE DIESEL ENGINES

The interaction of turbocharger characteristics with engine design and performance parameters is discussed. The matching of a turbocharger to an engine configuration by the choice of turbomachinery components is a very complex mix of performance and mechanical compromises. A variety of factors must be considered, each of which has an impact on all aspects of the overall package performance. Air-fuel ratios must be adjusted in order to optimize the engine combustion system performance. Firing pressures must be controlled to stay within the accepted boundaries for mechanical stresses in the hardware. The firing pressure limit controls the amount of turbine work that can be extracted in a given situation. These combined limits then control the transient response and torque peak-speed output. They also provide a limit to the torque rise attainable. The turbocharged engine characteristics are an interactive combination of the engine combustion system and mechanical design constraints and turbocharger characteristics. A series of tradeoffs must be optimized if the designer is going to achieve an overall acceptable performance for the system. In order to relieve some of the significant constraints on the system, efforts in turbomachinery design must concentrate on developing efficient, broad-range compressors which are driven by efficient, responsive, variable-geometry turbines.

TURBOCHARGER COMPRESSOR PERFORMANCE EVALUATION AND CRITICAL FLOW FIELD MEASUREMENTS

A detailed study of two commercial turbocharger compressor impellers (full-blade, and partial-blade or cutback) with a parallel-wall, vaneless diffuser was carried out to expand understanding of current turbocharger test procedures and to lay the groundwork for an "industrially useable" method to assess discharge conditions from radial turbomachinery rotors. The study demonstrated that present turbocharger compressor maps from different sources cannot be reliably compared because random errors can amount to plus/minus 0.05 (5 points) on efficiency (20:1 odds). Common sources of random error include uncalibrated thermocouples, stem errors, improperly formed pressure taps, and transducer and electronic processing errors. For the particular impellers and vaneless diffusers tested, a diffuser flow field was found for which the flow followed the diffuser rear (hub) surface at impeller discharge with backflow at the shroud; the pattern reversed midway through the diffuser with attachment along the front (shroud) and with reverse flow along the back wall (hub). The traverses were invaluable in deducing the flow field structure. Although the quantitative diffuser results were useful in providing upper and lower data bounds on basic parameters heretofore deduced (slip factor, backflow loss, rotor efficiency, diffuser recovery), difficult probe/measurement questions must be resolved before quantitatively precise results will be obtained. The full-blade impeller plus diffuser appeared to be slightly superior to the partial-blade impeller plus diffuser.

EXHAUST EMISSIONS FROM A EUROPEAN LIGHT DUTY TURBOCHARGED DIESEL

The impact of turbocharging on diesel exhaust emissions was investigated by studying a 4-cylinder, indirect injection (IDI) Fiat engine with different configurations (fuel injection optimization, exhaust gas recirculation (EGR), oxidation catalyst, turbocharging). Experimental results obtained during bench and chassis dynamometer tests were compared with the results from the same tests performed in the naturally aspirated (NA) 4-cylinder engine. Mathematical models were used in order to identify the regions maximally contributing to regulated emissions of HC (hydrocarbons), CO. (carbon monoxide), NOX (nitrogen oxides). Particulate and organic, adsorbed compounds were also measured. For a 3000-lb vehicle, it is concluded that emission targets equal to 0.41 g/mi HC, 3.4 g/mi CO, 2 g/mi NOX, and .7 g/mi particulate are achievable with the NA, IDI diesel engine; EGR is useful in lowering NOX (to less than 1.5 g/mi), but increases particulate emissions. Oxidation catalyst appears to offer levels of 0.41 g/mi HC, 3.4 g/mi CO, and 1.5 g/mi NOX with a particulate level of 0.7 g/mi, if a diesel fuel with low sulfur content is used. Turbocharging appears to be a good approach to achieve low gaseous emission levels of 0.41 g/mi HC, 3.4 g/mi CO, and 1.5 g/mi NOX with lower particulate emissions (less than 0.4 g/mi) CO, and 1.5 g/mi NOX are reasonable achievable with particulates less than 0.6 g/mi. Turbocharging plus EGR plus oxidation catalyst permit these same figures to be achieved more easily if a diesel fuel with low sulfur content is used, and also decrease the organic emissions.

TURBOCHARGERS FOR THE 1980'S--CURRENT TRENDS AND FUTURE PROSPECTS

The requirements placed on turbocharging systems in the very different applications of automobiles (gasoline and diesel), trucks, and off-highway vehicles are reviewed. The developments that will be required in the 1980's are highlighted, together with an analysis of current limitations and future potential. Prospective developments relate not just to turbocharging, but to matching, system design, and maximizing exhaust gas energy utilization. For the near future, development on trucks and off-highway vehicles at modest ratings will continue, with emphasis on wide flow-range compressors, efforts to increase low-speed boost, and better detail design of port and manifold systems. In the near future, the number of turbocharged gasoline engines will increase, although long-term success depends on their comparative cost-effectiveness as a fuel economy measure; this is likely to require a major breakthrough in production costs. The ceramic, variable-geometry turbine is the ideal for this application, if it can be developed to achieve reliability at low cost. More certain is the route of small turbocharger applications to passenger car diesel engines, particularly in Europe; these can benefit from developments aimed at the gasoline engine. In the U.S., stringent exhaust emission legislation is offset by the economies of larger production runs on each engine build. The high break mean effective pressure engine also presents problems to the turbocharger manufactures; high-pressure ratio turbomachinery is required with wide flow range, good efficiency, and durability. Problems encountered with such single-stage turbocharging such as inadequate low-speed torque, poor driveability, and matching for operation at altitude, may be avoided by introducing two-stage systems. In all applications, more emphasis is expected on detail design of all components in the total turbocharging system, including valves, ports, manifolds, and exhaust systems, as well as the turbocharger itself.

VARIABLE AREA TURBOCHARGER FOR HIGH OUTPUT DIESEL ENGINES

A program was undertaken to develop, build, and test an advanced turbocharger on the AVCR-1360 air-cooled diesel tank engine for the Army, by Teledyne Continental Motors, and Thermo Mechanical Systems. High-output, turbocharged diesel engines require efficient air-delivery systems with high pressure ratio, broad range, and surge-free compressors of very high efficiency, as well as high-efficiency turbines with variable stators, in order to maintain high turbine speed when engine speed and airflow are low. The turbocharger developed to meet these goals has a backswept centrifugal compressor with a wedge-type moveable vane diffuser for surge control and a radial inflow turbine with individually pivoted nozzle vanes for inlet flow-area control. After several design iterations and bench tests, extensive engine tests were conducted to demonstrate the substantial improvements in diesel engine performance that are attainable with these turbochargers. A peak engine torque of 3650 ft lb (4949 Nm) has been demonstrated by the AVCR-1360 engine equipped with variable-area turbocharger (VAT), compared to peak torque of 3120 ft lb (4230 Nm) for the base engine. The target torque rise at 1600 rpm of 20% above the rated 3050 ft lb (4135 Nm) has been achieved. The system has the capability of running at the full-speed rated torque at 50% engine speed. The VAT-EQUIPPED engine has a peak of 1660 gross brake hp (1228 Kw) at the rated 2600 rpm vs. 1500 (1110 Kw) for the base engine. Brake specific fuel consumption (BSFC) at the rated point has been demonstrated at .390 lb/GBHP-HR (237.2 g/Kw hr), about a 10% improve 5% improvement. Steady-state smoke observations indicate substantial smoke reduction. VAT durability has been demonstrated to a limited degree (about 700 hr of turbocharger operation without major failures).

HS-026 360

THE EFFECT OF COMPRESSOR AND TURBINE SPECIFIC SPEED ON TURBOCHARGER EFFICIENCY AND ENGINE PERFORMANCE

In a technique for optimizing turbocharger design, calculations demonstrate the effect of decreasing turbocharger component specific speeds on overall turbocharger efficiency. It is concluded that an overall turbocharger efficiency greater than 70% is obtainable for low specific-speed compressors and turbines, an improvement of at least ten points above the overall turbocharger efficiency of the best of current machines and 15 points above more typical modern designs. Since two points improvement in overall turbocharger efficiency corresponds to approximately one point in engine efficiency, an improvement in engine efficiency or specific fuel consumption in the order of five to seven points appears possible. The price of large, low specific-speed turbochargers for vehicular diesel engines is not known since vehicular turbochargers of this size have not been built. Larger turbochargers will present installation problems in many vehicular applications, and their rotary inertia will be greater than current designs. Although this will have an effect on the transient performance of the turbochargers, the decrease in transient performance may be reduced by the improvement in component efficiency.

CENTRIFUGAL COMPRESSOR DEVELOPMENT FOR A VARIABLE AREA TURBOCHARGER

A variable-geometry diffuser was developed for a centrifugal compressor with the objective of meeting the surge regulation and airflow requirement of the Army's advanced AVCR-1360 air-cooled diesel tank engine. The program involved the combined design and development activities of Teledyne Continental Motors (General Products Div.), Power Dynetics, Inc., and Thermo Mechanical Systems. Two types of compressor rotors were built and tested (a radial-blade impeller and a backswept impeller). Results of the performance test program indicated that the variable-geometry compressor met the range and efficiency goals over most of the required operating conditions. The backswept impeller was found to be superior to the radial-blade impeller over the entire operating map. Compressor efficiencies as high as 80% were demonstrated in the high airflow operating regime (rated engine speed). At very low airflows corresponding to the lowest engine speed operation, the onset of impeller stalling caused an efficiency loss. It is believed that the complexity of variable geometry is justified where maximum efficiency and range are mandatory. Continued development of the variable-diffuser, backswept compressor is necessary to upgrade the efficiency at the engine idle speed condition (1000 rpm). Such a development program should include inlet and impeller geometry changes, diffuser system refinements, and turbocharger modifications designed to increase the design specific speed of the variable-area turbocharger.

SERIES TURBOCHARGING--A REQUIREMENT FOR HIGH SPECIFIC OUTPUT, VEHICULAR DIESEL ENGINES

In view of the problems associated with obtaining broad compressor range and efficiency at high pressure ratio and the ever-present requirements for durable, low-cost, and low-inertia turbochargers, the performance benefits derived from series (two-stage) turbocharging as applied to high-speed vehicular diesel engine applications are examined. The efficiency, compressor range, transient response, and pressure ratio characteristics of series turbocharging are compared and contrasted to those of single-stage turbochargers. This comparison is fundamental because, in the size class of interest, no high pressure ratio turbochargers are currently in production. It is concluded that it is practical to use existing vehicular tubocharger technology to satisfy, at least in the near term, the demand for higher pressure ratio turbocharger capability. The present-day turbocharger, in volume production, can supply the building blocks for series turbocharger systems.

ESTIMATING THE INFLUENCE OF PULSATING FLOW CONDITIONS ON THE PERFORMANCE OF A TURBINE

A new method of estimating turbine performance under nonsteady flow conditions is described, based on the concept of "mean effective turbine expansion ratio" (m.e.t.e.r). The m.e.t.e.r concept is defined as that average expansion ratio which, when assumed to exist across a turbine working under nonsteady flow conditions, gives the "actual" turbine power, with other parameter values being time average values and the isentropic efficiency being a function of this average expansion ratio. A digital computer program to evaluate the "pulse factor" is presented; the pulse factor is evaluated to predict the turbine performance under nonsteady flow conditions when the performance under steady flow is known. This factor takes into account the variations in expansion ratio, mass flow rate, turbine inlet temperature, and turbine nominal efficiency due to nonsteady flow and is a linear function of mass flow parameter for a constant pulse frequency. The estimation method has been used successfully in real-time digital, hybrid, and analog computer simulations for predicting transient performance of a turbocharged diesel engine. Good agreement was found between predicted and test-bed results.

HELMHOLTZ TUNED INDUCTION SYSTEM FOR TURBOCHARGED DIESEL ENGINE

A tuned intake induction system using a Helmholtz resonator was applied to an in-line, 6-cylinder, 4-cycle, heavy-duty diesel engine, the system being designed to minimize the engine breathing performance at the peak torque engine speed. Significant advantages of this system were 12% improvement in volumetric efficiency, improved cylinder-to-cylinder air distribution, and faster turbocharger response. The increased trapped air-fuel ratio also resulted in improved combustion efficiency and reduction of smoke emissions. Additional improvements appear feasible by compressor redesign and optimization of valve timing. The primary disadvantages are the additional space requirement and corresponding installation difficulties, but compact designs can be achieved without great difficulty. The tuned intake resonator offers a means of improving the engine airflow characteristics by economical means. It performs this function without undue system complexity, moving parts, or the need for a control system. These attributes make its incorporation possible without compromising the reliability or durability of the powerplant.

SILENCER DEVELOPMENT AT TI CHESWICK SILENCERS [MUFFLERS]

Development approach, activities, and test facilities for exhaust systems at TI Cheswick, a British firm, are described. The general approach to muffler development is one of allowing the exhaust gases to expand into chambers of large cross-sectional area. Expansion of the relatively low frequency wave fronts, successively, into volumes adding up to one-third capacity (use of expansion chambers) is general practice. "Roughness" following in the wake of the wave front is reduced by use of louvered tubes within closed portions of the muffler; these tubes act as Helmholtz resonators to attenuate the high frequencies. One peak frequency in the combustion exhaust spectrum, called "boom", is often dealt with by a separate Helmholtz resonator. Gas-induced noise such as "pipe noise", case rattle, and plate vibration are usually overcome by such measures as laminated pipes, damped end-plates, increased number of bulkheads, and insulated case structures, while "overrun rasp" is normally treated with a resonator within 1070 mm (42 in) of the exhaust ports, or by passing the gas through an "absorption chamber" prior to expansion. TI Cheswick is also involved in the production canning of catalytic converters and in the development and testing of other promising pollution control devices. Latest systems are three-way catalytic converters; for the 1980 model year, oxygen sensors are to fitted, with electronic computer control of the engine air-fuel ratio. New systems are tested on thermal cycyling and thermal vibration rigs, with successful designs proceeding to engine dynamometer and on-car trials. Current units are made on company-designed, special-purpose machines. Parallel development work has been carried out on "lean burn" thermal reactors designed to replace conventional exhaust manifolds. The company, jointly with Texaco and Associated Octel, has developed a lead particulate filter for reducing lead emissions, and is developing a diesel particulate filter.

HEAVY DUTY DIESEL PARTICULATE EMISSION FACTORS

In an Environmental Protection Agency program over the past several years, particulate emissions have been measured from a variety of heavy-duty diesel engines. Samples have been collected by Southwest Res. Inst. using an exhaust splitter to divert a fraction of the engine exhaust into a standard dilution tunnel. A small fraction of the diluted exhaust from the tunnel is pulled through a filter from which particulate mass and, in some cases, organic content of the particulate is determined. The sampling system is discussed, and particulate emission factors are given that have been computed from truck and bus fuel consumption data. Average truck and bus speed data from New York and Los Angeles (freeway and nonfreeway usage) are also provided. Average particulate emission test results (steady-state tests) for 2-stroke engines are 4.74 g/kg fuel, and 2.64 g/kg fuel for 4-stroke engines. Using average particulate emissions results, a particulate emission factor range of 0.8 g/km to 1.3 g/km was computed. Nationwide diesel particulate emissions were calculated to be 88,170 metric tons per year (79,850 for trucks, 2750 for intercity buses, and 5570 for local buses).

FUNDAMENTAL STUDIES IN AUTOMATIC VEHICLE CONTROL. INTERIM REPORT

In the first year of a planned three-year program, the research efforts were focused principally on the development of an automated vehicle test facility which would be employed to study control and communication problems at, and below, the sector level. These studies would be focused on the automatic control of high-speed (to 28.1 m/sec), traffic operations at time headways as small as one sec. The primary activities included the implantation of both lateral and longitudinal information sources at the 6.4-km, skid-pad facility at the Transportation Research Center of Ohio; the specification of a sector-level controller which would be comprised of a commercially available microprocessor and a considerable amount of special-purpose hardware; a study of automatic longitudinal control, both in the normative and emergency modes of operation; the evaluation of a "flattened" helical-line information source for providing continuous position information to each controlled vehicle in a sector; and a study of automatic steering with an emphasis on high-speed, lane-changing operations. Details are presented of the first, third, and fourth activities; the other two will be discussed in two forthcoming papers. The secondary activities included a reevaluation of a headway safety policy for automated highway operations, and the development of a methodology to determine the accident costs associated with a particular policy choice.

PIERCING THE DRIVER LICENSE VEIL [NON-USE OR MISUSE OF THE NATIONAL DRIVER REGISTER IN ISSUING LICENSES]

Although most states participate in the National Driver Register (NDR) to some degree, four states (California, Florida, Massachusetts, and New York) issue about 25% of the driver's licenses in the U.S. with little or no prior use of the NDR. The NDR is a voluntary, cooperative Federal-state project providing a source of data which states can utilize to determine if persons applying for or renewing driver's licenses have had their driving privileges suspended or revoked in other jurisdictions. State laws prohibit issuing a license to a person while his license is withdrawn in another jurisdiction. Failure to use the Register raises the question whether the states are liable for damages if a driver who should not have been licensed is involved in a crash. A review is given of the reasons offered by the aforementioned states for not making full use of the NDR, and a commentary provided on the potential liability of these states.

INVESTIGATION OF THE INFLUENCE OF VARIOUS BRAKING REGULATIONS ON ACCIDENT AVOIDANCE PERFORMANCE. FINAL TECHNICAL REPORT

Passenger car braking regulations promulgated by the United States and various European countries were analyzed to determine the incompatibilities in brake proportioning that derive from the performance requirements of the regulations. Two vehicles were considered, one produced in the U.S. and the other in Europe, with extreme loading conditions (as derived from option selection and vehicle loading). The analysis shows that the European regulations (United Nations Economic Commission for Europe Regulation 13, Common Market European Economic Community Directive 71/320, Swedish regulation F-18) require a larger forward bias in brake proportioning than FMVSS (Federal Motor Vehicle Safety Standard) 105-75. Computer simulations were used to predict the following differences in braking performance which result from proportioning the example vehicles to comply with the different regulations: conditions of straight-line braking, braking in a turn, and three surface friction levels. In general, both vehicles were capable of achieving shorter stopping distances when proportioned to meet FMVSS 105-75 than when proportioned to comply with the European regulations, but the differences are considered trivial with respect to the ordinary driver. When proportioned to meet FMVSS 105-75, the rear wheels of the two study cars sometimes locked up first, a result that the European regulations are designed to prevent. Braking-in-a-turn test procedures (which have been discussed both in the U.S. and aboroad) were also studied through computer simulations and found to be relatively insensitive to the fore-aft proportioning of brake torques.

A DIGITAL ELECTRONIC SHIFT SCHEDULE CONTROL FOR VEHICULAR AUTOMATIC TRANSMISSIONS

A digital transmission shift schedule control has been developed which measures throttle position and vehicle speed to determine the proper gear ratio based on preprogrammed upshift and downshift schedules. Five- and six-bit vehicle speed and three- and four-bit throttle position resolutions have been evaluated. Throttle position was measured with an experimental variable-reluctance device (variable-frequency oscillator), located above the throttle position; vehicle speed was measured by a magnetic pickup from a toothed wheel on the transmission output shaft. The electronic control system has been evaluated for over 4000 mi under city, highway, sea-level, and high-altitude conditions. It has been demonstrated to be a viable method of scheduling the shift points of a transmission and represents a likely first step in the conversion of transmissions to electronic control. The best compromise resolution for vehicle speed would probably be a five-bit signal with full scale at 85 mph. The same speed signal would be used for 1-2 and 2-3 shift schedule. This would provide approximately 2.7 mph increments for both the 1-2 and 2-3 shift schedules. The best compromise resolution for throttle position would probably be a three-bit nonlinear signal. Every attempt should be made to minimize the number of external wiring connections, as the only durability/reliability problems encountered were with electrical connectors. The control should be integrated with a speedometer display and crusie control, thus eliminating all mechanical vehicle speed measurement.

COIL SPRING SERVICE

Diagnostic and servicing information is provided for the automotive service specialist concerning coil spring components of a suspension system. The design of a suspension system to work around a basic vehicle height, and the effect of sagging coil springs on alignment angles (and thus on tires and handling) are discussed. Badly sagged coil springs must be replaced to restore the car to the original ride height so the wheels can be properly aligned. Tips for measuring vehicle ride height as a diagnostic technique are given. Step-by-step procedures (and accompanying photographs) are provided for servicing coil springs mounted on upper control arms, on lower control arms, on twin axles, and on rear axles. In separate sections, general servicing tips are outlined, and a job cost comparison for a 1974 Chevrolet Impala is made among coil spring servicing, minor engine tuneup, minor brake job, and shock absorber tuneup.

STEP TO THE REAR [REAR AXLE SERVICING]

Information is provided for the automotive service specialist for diagnosing and correcting rear axle assembly problems. Instructions are given for a thorough test of a vehicle in order to isolate the source of the problem noise, and the characteristics of the two general types of rear axle noise (gear and bearing) are described. Step-by-step procedures are outlined for disassembling rear axle assemblies; information is provided for inspecting, reassembling, and making final adjustments. Differences between the two types of axle carriers (integral and removable) are indicated; the different components of the two types are illustrated, as well as their adjustment points. The final road test (the first one having taken place in the diagnostic stage) is described. A rear axle IQ test of 15 questions with multiple-choice answeres is included, and correct answers provided.

CLOSING THE LOOP [ELECTRONIC EMISSION CONTROL SYSTEM]

General Motors has a new emission control system, the Computer Controlled Catalytic Converter (C-4), which is used in California on some 1979 3.8-L V6's, 1980 2.5-L L4's, and 2.8-L V6's. The purpose of the C-4 system is to maintain the air-fuel ratio at the level where the 3-way catalyst is most effective. A bonus of the system is that it prevents the excessively lean mixtures that cause poor driveability. If the C-4 malfunctions, a built-in self-diagnostic system flashes a CHECK ENGINE light on the dashboard. The technician then grounds a trouble code test lead, and a number indicating the problem area flashes. A dwellmeter, ohmmeter, test light, digital voltmeter, tachometer, vacuum gauge, and jumper wires are the only tools needed to diagnose the system. The C-4 will keep a record of anything that goes wrong while the car is in use, and this memory can be queried when the car is brought into the shop. Among the features of the C-4 are an electronic control module, coolant temperature sensor, electronically controlled carburetor, and a distributor advance-retard system.

NBR VULCANIZATES RESISTANT TO HIGH TEMPERATURE AND "SOUR" GASOLINE

Cadmium oxide and zinc oxide activated low-sulfur cures and peroxide cures of NBR or poly(butadiene-co-acrylonitrile), with physical properties suitable for use in fuel-line hose tube, were compared with a compount typical of those now used in fuel-line hose to examine their resistance to aging by gasoline containing hydroperoxides ("sour" gasoline). NBR compounded in a conventional fuel hose tube formulation was found to be degraded markedly by sour gasoline or sour ASTM Fuel C within 7 days at 40 degrees C. The conventional NBR compound was not resistant to aging at 125 degrees C. Use of an NBR designed for heat-resistant compounding and an appropriate choice of compound greatly improved resistance to fuel which contained hydroperoxides. The perferred system for sour gasoline resistance and resistance to long-term aging at 125 degrees C is a cadmium-activated, low sulfur-sulfur donor compound with silica as the principal filler. This vulcanizate is not much more affected after 7 days at 40 degrees C by gasoline of peroxide number 50 than by clean gasoline, and is less affected by gasoline of peroxide number 200 than are other NBR vulcanizates. The balance of high- and low-temperature properties can be optimized by appropriate choice of plasticizer and acrylonitrile level. Aging resistance is improved somewhat by increase in acrylonitrile level, and fuel permeability is decreased markedly. Permeability to gasoline with 30 aromatic content can be changed appreciably by compounding, but the resistance to Fuel C with 50% aromatic content does not appear to respond to compounding changes. The stability of NBR vulcanizates in sour gasoline is reduced by copper salts and, to a lesser extent, by metallic copper. Bound antiozidant NBR does not appear to offer an advantage in sour gasoline resistance over heat-resistant NBR compounded in a comparable formulation.

FHWA HIGHWAY TRAFFIC NOISE PREDICTION MODEL. FINAL REPORT

The Federal Hwy. Administration method is described for predicting noise generated by constant-speed highway traffic. The report is designed as a users' manual and as a reference document, detailing the development, use, and limitations of the prediction method. The prediction procedure is presented, step-by-step, with example problems for highlighting important concepts and features. Appended is a detailed derivation of the model. The basis of the model is the equivalent sound level (Leq), although an adjustment for conversion to L10 is provided. Three classes of vehicles are included: automobiles, medium trucks, and heavy trucks. Adjustments for absorptive ground covers and finite-length barriers are also included, as are certain special topics, such as nonuniform highway sites and determination of equivalent day-night levels (Ldn).

INITIAL EXPERIENCE WITH A DRIVER IMPROVEMENT PROGRAM FOR TRAFFIC OFFENDERS WITH ALCOHOL-RELATED PROBLEMS (ERSTE ERFAHRUNGEN MIT EINEM DRIVER-IMPROVEMENT-PROGRAMM FUR ALKOHOLAUFFALLIGE VERKEHRSSTRAFTATER)

Initial experience with a driver improvement program for problem drivers is reported, the program oriented toward changing driver attitude and behavior. The program is based primarily on learning theory and applies such methods as behavioral analysis and self-control techniques. The program consists of four 2- to 2-●-hr sessions with small groups, with individual sessions at the beginning and conclusion of the program. The main topics of the course include the following types of driver impairment; underestimation of the hazardousness of certain traffic offenses, overestimation of one's driving capability, underestimation of the detrimental effects of alcohol, and inappropriate estimation of the consequences of one's behavior. Initial experience in testing the program involved a group of 25 male offenders with an average age of 30, almost all having been involved in alcohol-related accidents involving personal injury. Participant response, psychologists' evaluation, and comparison of personality and attitude questionnaire results before and after the group session indicate promise for the driver improvement program.

APPRAISALS OF VISIBILITY ON LIGHTED DRY AND WET ROADS

A study was made of the changes of visibility conditions on wet lighted roads compared with those on dry lighted roads, and to examine the possibility of adapting luminance design methods to the wet state. Considerable deterioration in the visibility of objects was found for the wet vs. the dry condition, but often the deterioration was not confirmed by observer subjective appraisals. The extentsion of luminance design methods to the wet state was found impossible. It is concluded that road lighting quality appraisals should be based directly on research studies of visibility on roads.

TRAFFIC SAFETY IN HIGHWAY CONSTRUCTION ZONES. PT. 1--PROBLEMS AND IMPROVEMENTS

A review of several studies comparing accident experience before and during highway construction activity demonstrates that there continues to be a traffic safety problem associated with construction zone traffic control practices. One method of improving traffic safety near construction is the effective planning and design of construction zones; the first two of five logical steps in this approach are outlined: determining basic conditions, and selecting basic zone type and scheduling. The basic conditions have to be identified by obtaining construction data (lateral location, length, and expected duration of construction), roadway data (e.g. cross section, number and width of lanes, shoulder width, roadside obstacle clearance, median width, horizontal and vertical alignment), and traffic data (e.g. traffic composition and volume, vehicle speeds). Selecting the basic zone type involves separating traffic and construction activity in space and/or time. Space separation is accomplished by one of the following zone types: lane closure, crossover, temporary bypass, detour, or roadside work zone. Separation in time is accomplished by restricting either traffic or construction activity time. Entering what is covered in another item creates false drops.

HS-026 379

TRAFFIC SAFETY IN HIGHWAY CONSTRUCTION ZONES. PT. 2--SPEED CONTROL STRATEGY

The last three steps in the effective planning and design of highway construction zones are outlined formulating speed control strategy, determining geometric design elements, and selecting traffic control devices and methods, and the effective management and operation of construction zones are discussed. The two main philosophies of speed control are maintenance of normal speed, and reduction of speed. Once the speed control strategy has been chosen, the construction travelway should be designed according to the geometric design standards required for the traffic speed; several principles to be followed in geometric design are outlined. The fifth and final planning and design step is the selection of appropriate traffic controls; their appropriate use is described, as well as several new devices developed to control traffic through construction areas. Zone management is discussed in terms of advance public warning, personnel training, zone operation evaluation, removal or alteration of inappropriate traffic controls and signs, movement of warning signs to keep pace with construction activity, and maintenance of traffic devices.

THE DIESEL DILEMMA; EPA'S ENVIRONMENTAL PROTECTION AGENCY DIFFICULT DECISION

The future of the diesel car is discussed in terms of its particulate emissions and their potential carcinogenicity. In light of inconclusive findings of laboratory studies conducted by the Environmental Protection Agency (EPA) on the carcinogenic effects of diesel exhaust, both EPA and the auto industry (General Motors in particular) are increasing their research efforts. When some preliminary results will be available at the end of 1979, the EPA Administrator will decide, based on possibly very meager data, whether to allow or to ban continued production of diesel passenger cars. The diesel gets about 25% better fuel economy than the standard gasoline engine, but faces a problem in meeting emission standards. Particulate matter, nearly 0.5 kg/1000 mi of city driving, is the major emission concern. These bits of aggregated carbon (common soot) not only create odor and visibility problems but nearly 95% of them are coated with potentially harmful hydrocarbons. These particles are presently unregulated, although a standard has been proposed and may be promulgated by EPA at the end of 1979. Despite the lack of any successful particle-control technology, and the existence of many unanswered health questions, especially preliminary evidence that diesel particles may cause cancer, industry is tentatively moving ahead. The few epidemiological studies to date have not demonstrated direct links between diesel exhaust components and cancer nor have they vindicated diesel emissions. EPA will probably tell industry that there is insufficient evidence on which to ban diesels but that, in order to continue to produce diesel cars, industry must meet a particulate emissions standard (likely to be 0.6 g/mi for 1981 model year cars). Despite GM'S recent protests to the contrary, this standard can be met by diesel manufacturers, although not easily. Although the 0.6 g/mi standard may not be adequate to protect public health, EPA can still appear to be doing something about public health.

HS-026 381

A FUNDAMENTAL CONSIDERATION ON SHIFT MECHANISM OF AUTOMATIC TRANSMISSION

A new shift mechanism for three- or four-speed automatic transmissions, compact in design and having a better shift quality, has been designed which consists of a single planetary gear set, two clutches, and an overrunning clutch mounted on the planetary input member. The ring gear member is detached from the turbine member by the overrunning clutch during the power-off upshift and the power-on downshift; it is therefore easy to control the timing of clutch engagement and disengagement. Refinement of the shift control method involves a shift valve for controlling the hydraulic pressure applied to the clutches and two timing valves for controlling the engagement/ disengagement timing. Theoretical and experimental studies have demonstrated that the new shift mechanism provides a better shift quality, and that the shift characteristics are remarkably affected by the vehicle vibration system, especially the torsional vibration of rear axles, the axle windup, and the engine fore and aft vibration. The new mechanism has been successfully applied to a Toyota four-speed automatic transmission with overdrive.

A HEADWAY SAFETY POLICY FOR AUTOMATED HIGHWAY OPERATIONS

The maximum capacity, cost, and safety of an automated highway system are largely dependent on the selected headway policy, i.e. the specification of a minimum acceptable headway (as a function of speed) for mainline operations. A policy, designed to avert collisions due to "reasonable" lead-car decelerations, is presented and evaluated in the context of achieving high capacity (greater than or equal to 3600 vehicles/lane/hr) over a range of typical highway speeds (13.5 m/sec to 30 m/sec (30.2 mi/hr to 67.2 mi/hr)). A detailed analysis was made to determine both the relationships among, and the requirements on, seven parameters requisite to this policy which pertain to systems-level operations, the capabilities of a vehicle's automatic control system, and the vehicle/roadway interface. The tradeoffs associated with safety, capacity, and cost (in the form of required future development efforts) are identified, and three general approaches to selecting parameters for an operational system are specified.

"SAFE-APPROACH" VEHICLE-FOLLOWER CONTROL

A "safe-approach" operating policy for automated guideway transit systems is presented which specifies velocity/spacing relationships for dynamic string operation. This policy is compared with steady-state policies such as constant time headway, constant separation, and constant K-factor. It is shown that only the safe-approach operating policy is consistent with collisionless service maneuvers. A description is given of how such a safe-approach policy can be used to implement vehicle longitudinal control systems. An example control system is discussed, which uses a basic velocity control loop for all overtaking and headway control operations. Simulation results are included to demonstrate the performance of this design. Ways are discussed in which the safe-approach policy may be further extended to handle emergencies and merge/diverge operations.

ATTITUDES OF VIRGINIANS TOWARD TRANSPORTATION SAFETY. RESULTS OF THE 1978 TRANSPORTATION SAFETY PUBLIC OPINION POLL. FINAL REPORT

In Oct and Nov 1978, approximately 2000 randomly selec
Virginia families were called and a member of each househ
over the age of 16 was asked his opinion on various transpo
tion safety issues. About 80% of the respondents felt that
sons convicted of drunk driving would benefit from an alc
treatment program. A slight majority (53%) favored a l
drinking age (for beer) of 18, with about 27% preferring
years; slightly more preferred 21 years to 18 years as the
restriction for wine. An overwhelming majority (about 9
felt that driver education should be a prerequisite for per
obtaining a license before turning 18. A majority (74%)
favor the maintenance of a 55 mph speed limit. A majo
(86%) was found to approve of periodic motor vehicle ins
tion. Over 90% of the respondents (and over 76% of moto
clists polled) were in favor of mandatory helmet use by mo
cyclists. Only 33% of the respondents favored a mandatory
belt usage law (a figure lower than in a 1977 survey), w
more people (55%) than in the previous year favored ma
tory installation of passive restraints. Of the respondents,
felt that adequate progress had been made in improving
highways. The most common stated cause of railroad g
crossing accidents was dangerous practices by motorists.

THE USE OF RESTRAINTS BY CHILDREN IN AUTOMOBILES. N.R.M.A. [NATIONAL ROADS AND MOTORISTS' ASSOCIATION] SURVEY:

Results are presented of an Oct-Nov 1977 survey in which 1300 vehicles containing 1677 children were observed in seven shopping centers in Sydney (N.S.W., Australia) to determine child restrain availability and usage. Restraint systems were available to 85.5% of the children observed (child seats and harnesses to 48.7%, adult lap or lap-sash belts to 36.8%). Only 48.9% of the children wore a restraint (43.8% with a child restraint, 5.1% with an adult restraint), with only 43.5% considered to be adequately protected. The number of unapproved child seats decreased from 104 in a 1976 survey to 69. Although 58.4% of the 6-mo to 4-yr age group were adequately protected, only 19.3% of the 4- to 7-yr age group were so protected. In only 16 of 49 cases had an attempt been made to restrain bassinets. Compared to the 1976 survey, the number of children adequately restrained showed a 10.5% increase, but remains relatively low. The introduction of new child restraint legislation in N.S.W. in Mar 1977 may have encouraged more parents to place their children in the rear seat and to purchase child restraints, but has failed to impress on parents that if no child restraint is available, the child one year of age or older must wear an available adult seat belt.

ASSESSING THE NATIONAL 55 M.P.H. SPEED LIMIT

The desirability of the new national speed limit is evaluated, using tools of normative and positive economic analysis. The theoretical case for a speed limit is analyzed, and it is concluded that externalities in driving may justify the use of a speed limit, among other policies. The principal costs and benefits of the 55 mph speed limit are discussed, and available data are used in order to suggest reasonable estimates of costs and benefits. A number of conceptual and empirical limitations of the analysis are emphasized. Although the empirical analysis indicates that the benefits of the program outweigh the economic costs, a speed limit appears to be a second or third best policy for achieving both highway safety and fuel conservation goals. Other policies, aimed directly at these goals, might be more effective and could also eliminate the present inequity of penalizing, in terms of time costs, drivers of efficient compacts and gas guzzlers alike. Several possible policies which could be used to replace or, more likely, complement a national speed limit are gasoline price increases, taxation of cars on the basis of rated fuel consumption, mandatory seat belt usage, and mandatory installation of air bags in new cars.

BIKE AND CAR ACCIDENTS: PROBLEMS AND COUNTERMEASURES. SOME PRACTICAL ADVICE FOR CYCLIST AND MOTORIST

An in-depth study sponsored by the National Hwy. Traffic Safety Administration of almost 1000 bicycle/motor vehicle accidents in several U.S. states has classified the accidents into 36 problem types, and a brief review is given of 7 types which caused 49% of the fatal and 52% of the nonfatal accidents. The problems, their representation in fatal and nonfatal accidents, and countermeasures are outlined. The accident types include emerging from a driveway without slowing or stopping; failure of bicyclists to slow or stop for stop signs at intersections; motorist entering street from a commercial driveway, stopping and scanning, but failing to see bicycle approaching from left or right; motorist stopping for a stop sign and then hitting cyclists proceeding into or across street that has no stop sign; motorist colliding into the rear of a bicycle going in the same direction (failure to observe bicycle because of darkness, high closing velocity, driver's expectation that road would be clear of bicycles, and inadequate lighting of bicycle); bicyclist riding on right edge of road turns toward left without looking to rear or signaling and collides with overtaking motor vehicle; and motorist turns left into path of bicyclist coming in his direction.

MANDATED FUEL ECONOMY STANDARDS AS A STRATEGY FOR IMPROVING MOTOR VEHICLE FUEL ECONOMY

Following an overview of U.S. standards legislation for the three major motor vehicle policy areas (fuel economy, emission control, and safety), a review is presented of the legislative and administrative history of the mandatory fuel economy standards (National Hwy. Traffic Safety Administration rulemaking on fuel economy for passenger cars, 1981-1984, and for light trucks, 1980-1981), and the potential of such standards for achieving further improvements in new car fleet fuel economy is assessed. It is concluded that mandatory fuel economy standards have proved to be a powerful and flexible instrument for increasing motor vehicle fuel economy, and are likely to be employed further. Since it is not possible at the start of rulemaking to assess properly all the impacts of a regulatory decision, continuous reappraisal of proposed standards will be required as new information and knowledge are provided by interested parties. If, in the post-1985 decade, mandatory fuel economy standards are to continue as a useful strategy for fuel economy improvements, they will have to be supported by other Federal policies both to stimulate the marketability of fuel-economy motor vehicles and to mitigate the adverse economic effects on certain industrial sectors, regions of the country, and segments of the work force.

BEYOND AUTOCRACY: THE PUBLIC'S ROLE IN REGULATING THE AUTO

A call is made for the Federal government to fund a long-term program to involve the public in transportation policy decisions. It is suggested that the National Hwy. Traffic Safety Administration (NHTSA), for example, expand its demonstration program to support public participation in rulemaking procedures, and that government should encourage the development of a corps of technicians who can evaluate, independently of government and industry, such matters as automobile safety, emissions control, fuel economy, public transportation, and transportation planning and use. It is proposed that the academic community interest itself in such issues as the social impact of the car. The automotive industry's economic clout with the media is seen in need of investigation and reform. It is pointed out that no organized grass-roots movement exists to oppose unregulated automobile production and the auto's indiscriminate use, and there are too few public interest and environmental organizations to compete adequately with the industry's special interest groups. Several major studies on the social impact of the automobile are deemed biased because of special interest overrepresentation. The NHTSA recognition of independent data and its support of public participation in Federal rulemaking procedures are cited. It is felt that the automobile as a consumer product is slowly coming under reasonable regulation. It is emphasized that a major regulatory failure has been the limitation of regulations to standardization of automobile components, and that consideration must also be given to the societal costs of auto-related air and water pollution, congestion, accidents, medical expenses, and government subsidies. The importance of a holistic approach to regulating the auto industry is emphasized, i.e. regulations in terms of the industry's products (through emission and safety standards), and in terms of how its products are used (through comprehensive and open planning processes).

TOWARD MORE EFFECTIVE ORGANIZATION FOR PUBLIC REGULATION

The issues of "institutional capacity" and strategy as related to government regulatory agencies and private industry (with particular reference to the auto industry) are addressed by exami ing the regulatory process. It is postulated that managers in th private sector and policymakers in the public sector typical lack specific and well-articulated strategies for dealing wi regulatory realities. Managers, it is said, often see regulatio narrowly in terms of increased dollar cost and uncertaint failing to recognize the legitimacy. Managerial significance, an competitive implications of regulatory actions. Policymake have an equally narrow view of regulations as either an admi istrative or policy problem, failing to recognize the diversity legitimate competing interests that are created by regulatio and expressed in the dynamic process of economics and politic The lack of attention to issues of institutional capacity an regulatory strategy is seen as related, at least in part, to generally poor understanding of the complex nature of the reg latory process. The regulatory process is described as intera tive, dynamic, and very sensitive to micro-level impacts, chara teristics which have important implications for the type of ana ysis required for effective regulation, the structure of public an private institutions, and the behavior and attitude of individu participants in the regulatory process. It is argued that befo they can develop adequate strategies, public and private mana ers must have better tools of analysis to assess the dynam characteristics of the regulatory process. All parties in the reg latory process also must distinguish analysis from decision, an must further distinguish decision from strategy. Analysis esta lishes the terms of trade among society's many conflicting o jectives; decision is at least partly an expression of preference policy strategy is a means of marshalling and organizing scar organizational resources so that over time the cumulative effe of individual decisions will lead to the desired ends.

INTERNATIONAL COMPETITION IN THE WORL AUTOMOTIVE INDUSTRY

Following a review of the market changes in the world's au manufacturing centers, U.S., Western Europe (U.K., German France, Italy), and Japan in the 1960's, the factors influenci international competion in the world automotive industry tod are examined. In that decade, market requirements were t main forces determining international competition, but in t 1970's, government policy has emerged as a primary influenc The role and effects are analyzed of the government as legis tor in the U.S., as owner in Western Europe, as promoter Japan, and as initiator in developing countries. Governme intervention in various forms is playing an increasing role in t pattern of international competition. Except for the U.S., go ernment intervention tries to aid its domestic motor industry protecting employment and/or encouraging investment. T U.S. policy is to implement legislation to protect the motor and conserve energy, which does not necessarily help its au industry. All the leading automotive producers have increasin ly to evaluate the various economic and political factors in the marketing strategies; these decisions are likely to be increasing directed towards investment rather than trade. Important que tions arise as to the continued legislative policy of the U. without the need to resort to some form of auto industry pr tection, and as to other governments' implementing environmental, safety, and fuel economy measures as in the U.S.

AUTOMOBILE EMISSIONS CONTROL POLICY--SUCCESS STORY OR WRONGHEADED REGULATION?

The Federal automobile emission control policy is criticized as having undesirable characteristics, and it is argued that a program of effluent fees would eliminate most, if not all, of the unfavorable aspects. It is acknowledged that progress has definitely been made in emissions control technology in the past decade, but that this progress has been slower and more costly than necessary. The gradual phasing in of the emission standards for hydrocarbons, carbon monoxide, and nitrogen oxides had denied the auto industry the learning curve benefits from a long experience with one set of standards. The inflexibility of the standards approach discouraged the introduction of diesels and other alternative engines. Cars in use generally have not been attaining the certification standards; since the standards apply solely to the sale of new cars, car owners have no incentive to maintain their vehicles to achieve low emissions. Currently only a few states and local communities have mandatory inspection and in-use standards programs. The basic logic underlying an effluent fee is that polluters ought to be made to pay the marginal social costs of their polluting activities. By keying fees paid to actual emissions, such a policy allows individuals to take the most efficient actions open to them. If pollution avoidance is expensive, they will choose instead to pay the fee. If the fees are have an incentive to take avoidance actions; if pollution avoidance is expensive, they will choose instead to pay the fee. If the fees are properly structured to represent the marginal social costs of pollution, either choice represents an efficient outcome. Fees would be applied to all motor vehicles in use and on all easily measured harmful pollutants Fees would be based on short emissions test conducted annually, the amount paid based on mileage driven in the previous year, emissions levels, and particular fee schedules set according to local pollution problems. Individual car owners and automakers would both have incentives for "clean" cars.

MULTINATIONAL AUTOMOBILE ENTERPRISES AND REGULATION: AN HISTORICAL OVERVIEW

The history of multinational automobile enterprises (U.S., European, and Japanese automakers) and the influence of government regulation is traced for the pre-World II period, the Inter-War years, 1945-1970, and recent times (1968-1978). Government regulations of various sorts have had, and will continue in the future to have, an important influence on the industry in the U.S. and abroad. What is distinctive today seems to be the new and imposing impact of the particular regulatory measures concerned with safety, pollution, and expecially energy, on a thoroughly multinational industry. The specter of varying forms of trade restrain seems present; these restraints are bound to create distortions in international markets. All these national regulatory actions can have unanticipated consequences, unless policymakers view them in the context of multinational automobile enterprises operating through investment and licensing as well as trade in an increasingly intergrated worldwide auto industry.

STATUS OF THE AUTOMOTIVE SUPPLY INDUSTRY: A REVIEW OF INDUSTRY TRENDS FROM THE TRADE LITERATURE

Through a review of the trade literature, the present situation of the U.S. automotive supply industry is analyzed in view of the changing needs of the automakers in meeting Federal emission, fuel economy, and safety standards. The problems facing the auto suppliers include uncertainty in the auto market, squeeze on profits, emphasis on primary materials and electronics technology, ambiguity of Federal regulations, and influx of foreign auto suppliers. The response of auto suppliers to these problems is discussed in terms of marketing strategy, capital investment decisions, management organization and research and development strategy. The role of the auto suppliers, automakers, and Federal government in increasing the auto supplier's contribution to technological innovation in the automotive industry is addressed. The auto suppliers will need the ability to understand and work with government, to understand and respond to changing industry economics, and to correctly perceive the consequences of government regulation. They will also need to improve their interface with other suppliers and the auto companies. The automakers may also be able to improve their working relationship with the auto suppliers. It is incumbent upon the auto companies to reduce wherever possible the high risks and costs of the automotive original equipment market. The areas deserving government attention include product liability, international trade, antitrust activity, inconsistent regulations and enforcement, and incentives for innovation.

CRASH VICTIM EXTRICATION TRAINING COURSE. EMERGENCY MEDICAL TECHNICIAN. STUDENT'S MANUAL. REV. ED.

This student manual is the primary text (study materials and later reference source) for a training course for emergency medical technicians (EMT'S) which addresses the problems of light rescue, specifically those involved in extricating people from automobiles and buses. Although designed basically for EMT'S, this course also meets the requirements for teaching light-duty extrication methods to rescue and safety personnel who have completed the National Hwy. Traffic Safety Administration (NHTSA) First Responder Training Course. Specific objectives of the course are to teach EMT'S their role and responsibilities in extrication; to develop their skill in analyzing the accident situation, stabilizing, gaining access, instituting life-saving emergency medical care techniques, disentangling, and removing the injured victim from the wreckage; to develop their skill in the use and care of extriction and related tools and equipment; and to develop their awareness of the hazards which may be encountered at the accident scene. The course comprises five lessons involving 16 hours of instruction, and testing, and is designed to be taught in a two-day period. Desirable qualifications for EMT'S who attend the Crash Victim Extrication Course are: satisfactory completion of the NHTSA Basic Training Course for EMT--*AMBULANCE or equivalent, or the NHTSA First Responder Training Course; a desire to expand basic extrication knowledge; ability to work as a team member, and to analyze a situation accurately, and take or suggest an effective course of action; and meet state qualification standards.

CRASH VICTIM EXTRICATION TRAINING COURSE. EMERGENCY MEDICAL TECHNICIAN. INSTRUCTOR'S MANUEL. REV. ED.

This instructor manual is to assist course coordinators and other individuals in organizing and implementing a course of study which addresses the problems of light rescue (i.e. extricating accident victims from automobiles and buses) by emergency medical technicians (EMT'S). The manual contains an outline of the course, instructor and student qualifications, classroom and demonstration equipment requirements, guidelines for conducting the course, and recommendations for student evaluation. Although designed basically for EMT'S, this course also meets the requirements for teaching light-duty extrication methods to rescue and safety personnel who have completed the National Hwy. Traffic Safety Administration First Responder Trainin Course. Specific objectives of the course are to teach EMT'S their role and responsibilities in extrication; to develop their skil in analyzing the accident situation, stabilizing, gaining acces instituting life-saving emergency medical care techniques, disentangling, and removing the injured victim from the wreckage to develop their skill in the use and care of extrication an related tools and equipment; and to develop their awareness o the hazards which may be encountered at the accident scene The course comprises five lessons involving 16 hours of instruction, demonstration, individual participation, and testing, and i designed to be taught in a two-day period. Recommended clas size is 24 students, with at least one instructor aid for each eigh students during practice and demonstration periods. The lea instructor and instructor aides should be certified EMT'S, thoroughly knowledgeable in the information and skills for the particular lesson period. Personnel from fire, rescue and ambulanc services with extensive experience in extrication procedure should be utilized. Each lesson plan contains performance objectives, references, equipment and materials, content outline, demonstration outlines, practice sessions, and skill evaluations components. It is recommended that each student be evaluated o skill proficiency at the completion of each lesson (skill evaluation sheets provided); pop quizzes at the end of each lesson an a final written exam on knowledge objectives are also recommended.

STOCHASTIC ANALYSIS OF FUTURE VEHICLE POPULATIONS. FINAL REPORT

Purpose of this study was to build a stochastic model of futur vehicle populations, useable in investigating the uncertaintie inherent in Future Vehicle Populations. The model, called th Future Automobile Population Stochastic Model (FAP Model), consists of two major components: a model of new ca sales, the model of automobile demand developed by Wharto Econometric Forecasting Associates, revised to incorporate th new vehicle survival model that was developed; and a procedure for specifying future planned and unplanned events, whic specifies the future values of exogenous parameters of the mod and incorporates the uncertainty of these parameters into th model. A computer program of the FAPS/MODEL was wri ten and is documented in the report. Also appended are survey of earlier and recent models, with bibliography, notes o the Weibull distribution, and a brief discussion of the innovations in the FAPS model.

ANALYSES OF SELECTED AUTOMOTIVE PARTS AND ASSEMBLIES FOR COST AND MATERIAL IMPACTS. FINAL REPORT

Manufacturing cost data, including all of the elements of cost (fixed, variable, tooling), as well as production processing information is presented for a wide variety of automotive components and assemblies. A representative vehicle, a 1975 Chevelle, was disassembled and analyzed on a part-by-part basis. The various cost elements which comprise total manufacturing cost were calculated, applicable processing methods determined, material analyses completed, and other pertinent information compiled. The process, cost, and material information is presented in various formats. All information reflects the current automotive production methodology. Comparisons of costs and materials of engine and transmission parts are provided for the 1975 Ford Pinto, 1975 Chevelle, 1976 Audi 100LS, and 1976 VW Rabbit. A review is included of generally accepted cost analysis techniques used by automotive companies to develop comparative, or target, costs. The various methods are discussed, including those using the cost data bank information, detailed manufacturing process cost techniques, and sign variance. Process descriptions of the selected vehicle and engine/transmission parts include the number of process operations, material, grade of material, rough and finished part weights, cost of raw material, variable cost, and other cost elements. Groupings by physical characteristics, material, and manufacturing processes are used to study the cost effects for various types of similar parts from different vehicles. Other studies are included to illustrate the cost impacts of alternate materials on various components.

STUDY AND TEST TO CONFIRM AUTOMOBILE DRIVETRAIN COMPONENTS TO IMPROVE FUEL ECONOMY. VOL. 1, HISTORY OF THE AUTOMOBILE TRANSMISSION IN THE UNITED STATES. INTERIM REPORT

An interim report presents a study of U.S. automatic transmissions, exploring the design from the earliest manual sliding gear transmission up through the various forms of automotive gear boxes, with emphasis on the development of the automatic transmission. It contains, in tabular form, a description of the 1970-1975 engine/transmission/rear axle ratio/vehicle size and weight combinations available in all U.S. cars of this time period. Included are early developments, the evolution of the self-shift, development during the 1920's and new techniques in the late '20s and '30s, evolution, elements and family tree of the modern automatic transmission, with numerous diagrams.

JUVENILE COURT ALCOHOL SCHOOL EVALUATION. INTERIM REPORT, SEPTEMBER 29, 1976 TO JUNE 1, 1977

Following an overview of project background and operation, results are presented of an evaluation of the Utah Juvenile Court Alcohol School, based on an analysis of 30% of the data after six months of operation. The School, begun in 1976, is an educational program attended by random juveniles convicted of alcohol offenses, and their parents. The School consists of five-weekly, two-hour educational sessions; the changes in the school participants are measured by pre-, post-, and six-month follow-up questionnaires and record checks. For evaluation purposes, three juvenile/parent groups have been established in addition to the School Group; they are the Contact Group (use of five one-hour sessions), the Regular Group (court alternatives applied), and the Cohort Group (general juvenile population comparison group). Findings are presented for three treatment groups (and comparison group, where applicable) based on questionnaire responses which have been grouped under the following categories: background demographics, cohort demographics, criminal history, driving history, teen driver responses, treatment motivation, self-perception, family life perception, parental support of juveniles, juvenile perception of parental support, parental support of juvenile decision making, juvenile control, parent control, communications, socialbility level with peer relationships, alcohol knowledge, attitude toward use of alcohol. The interim evaluation revealed that data categories which showed no pre-post difference were about equal to those with interesting and statistically significant differences. Appendixes contain pre-, post-, and follow-up questionnaires for the Juvenile Alcohol School, and questionnaire response evaluation approach; evaluation file design for the Statistical Package for the Social Sciences, data keying format, data control procedures, and data collection coding forms; and the Juvenile Alcohol School Facilitator Manual.

DEVELOPMENT OF A MOTOR VEHICLE MATERIALS HISTORICAL HIGH-VOLUME INDUSTRIAL PROCESSING RATES COST DATA BANK [FOR THE] (3500-4000 POUND) FULL SIZE CAR. FINAL REPORT

Efforts toward identifying and establishing a Motor Vehicle Materials High-Volume Industrial Processing Cost Data Bank for the 3500-4000 pound Full-Size Car were a macro- and micro-analysis, in which various costs were generated using an industry type estimating technique. In the micro-analysis method, a 1978 full-size production vehicle (Chevrolet Impala) was obtained and dismantled, and its various components and subassemblies analyzed in detail to determine the weight and estimated manufacturing cost associated with each item. From this basic data, other categorical costs were estimated, both in total for each item and on a cost per pound basis. The various items were grouped into several levels of assemblies on a basis of practiced industry groupings to arrive at total cost categories for a complete vehicle. The macro-analysis served as a means to provide data in certain areas to substantiate the microanalysis, involving the detemination of various average costs by a study of the past five years of historical financial records of the automotive corporation. Appendices include the micro-analysis cost data, the macro-analysis of General Motors records, and photographs of components for use in future cost study comparisons. Additional studies are recommended on other market classes defined by weight and cost.

IMPACTS OF MOTORCYCLE HELMET LAW REPEAL IN SOUTH DAKOTA: EXECUTIVE SUMMARY. FINAL REPORT.

Changes in levels of helmet use and in types of injury sustained by motorcycle accident victims between pre- and post-repeal periods of the South Dakota mandatory helmet law are described. Statewide surveys of helmet use in 1976 (pre-repeal) and in 1977 (post-repeal) involved the observance of 25,054 cyclists. Overall levels of helmet use were found to have dropped from 99.6% in 1976 to 57.3% in 1977 for cycle drivers, with a decline from 99.3% to 60.7% for passengers. Decreases in helmet use were large and significant for all times of day, days of week, and roadway types. Analysis of medical records data for motorcycle accident victims showed statistically significant increases in the incidence of head/skull injuries between pre- and post-repeal periods and between helmeted and unhelmeted drivers. Recorded levels of injury severity were significantly higher for unhelmeted drivers in both periods. Despite significant changes in incidence of head injuries, the statewide fatal, injury, and total crash rates were not substantially different between pre- and post-repeal periods.

ANALYZING THE FEASIBILITY OF THE ADMINISTATIVE ADJUDICATION OF TRAFFIC OFFENSES. VOL. 2. FINAL REPORT

Information is provided to aid analysts in assessing the costs an benefits of the administrative adjudication of traffic offenses i state and local jurisdictions. Issues are discussed related to th organization, management, and presentation of findings of feasibility study. Checklists of the types of benefits and cos that should be considered are presented, with data and exampl to aid in making quantitative estimates. Issues that normall would be addressed in a benefit-cost analysis of alternative adj dicative systems for traffic offenses include basic arguments fo administrative adjudication, legal and constitutional issues, a ticipation of special interest group concerns, the monetary an nonmonetary treatment of benefits and costs, and the treatme of traffic safety issues. Appendices contain additional materi on the technical aspects of a benefit-cost analysis of ministrativ adjudication, formats for the illustration and presentation findings, and other supporting information.

DEVELOPMENT OF COMPLIANCE TEST FOR TRUCK REAR UNDERRIDE PROTECTION. TASK 5 REPORT OF TESTS 5.1, 5.2, AND 5.3. INTERIM REPORT

Results are presented for the first three of eight vehicle-to-tru rear underride guard crash tests designed to test the effectiv ness of selected new guard designs in rear underride collisio with current production full- and small-size passenger cars. T tests are to provide a basis for selecting the best underride gua with regard to such critical parameters as geometric desig strength, energy-absorbing capabilities, and economic and env ronmental factors. The test vehicles (1978 VW Rabbits and 1978 Ford Fiesta) were impacted (about 40 mph) into bolt-o rigid, cantilevered guards mounted to a truck/trailer body sim lator (a modified 1977 Fruehauf 40-ft, heavy-duty platform tra er with Select-A-Point tandem rear wheels). For the three sy metric tests, two instrumented 50th percentile Part 572 anthr pomorphic dummies were placed in the driver and front passe ger positions in the car, and were restrained with the vehicl restraint system. The seat tracks were welded in the midpositi to prevent breakaway and/or rotation.

DEVELOPMENT OF COMPLIANCE TEST FOR TRUCK REAR UNDERRIDE PROTECTION. TASK 4 TEST REPORT. INTERIM REPORT

Results are presented for six vehicle-to-truck rear underride guard crash tests (four symmetric and two offset) designed to establish baseline parameters under present conditions with current production full- and small-size passenger cars. The test vehicles (1978 VW Rabbit and 1978 Chevrolet Impala four-door sedans) were impacted (about 30 mph and about 40 mph) into a bolt-on underride guard (Fruehauf Part No. FCE-1456-1) mounted to a truck/trailer body simulator (a modified 1977 Fruehauf 40-ft, heavy-duty platform trailer with Select-A-Point tandem rear wheels). For the six tests, two instrumented 50th percentile Part 572 anthropomorphic dummies were placed in the driver and front passenger positions in the car, and were restrained with the vehicle's restraint system. The seat tracks were welded in midposition to prevent breakaway and/or rotation.

DEVELOPMENT OF COMPLIANCE TEST FOR TRUCK REAR UNDERRIDE PROTECTION. TASK 3 TEST REPORT, INTERIM REPORT

Results are presented for two vehicle-to-truck rear underride guard crash tests (one symmetric and one offset) designed to provide data for establishing criteria for future tests in a program for the compliance testing of rear underride guards. The tests approximately model the rear of chosen truck trailer bodies to the extent of providing repeatable and indicative dynamic test results. The test vehicles (1966 full-size Ford Galaxy four-door sedans) were impacted (about 40 mph) into a bolt-on underride guard (Fruehauf Part No. FCE-1456-1) mounted to a truck/trailer body simulator (a modified 1977 Fruehauf 40-ft, heavy-duty platform trailer with Select-a-Point tandem rear wheels). For the two tests, one uninstrumented 50th percentile VIP anthropomorphic dummy was placed in the driver position in the car, and was restrained with the vehicle's restraint system. The seat tracks were welded in the midposition to prevent breakaway and/or rotation.

IMPACTS OF MOTORCYCLE HELMET LAW REPEAL IN SOUTH DAKOTA. VOL. 1. FINAL REPORT

The S. Dak. statute mandating helmet use by motorcyclists was modified, effective 1 Jul 1977, to effectively repeal the law for adult cyclists. Changes in levels of helmet use and in state-wide accident experience are assessed between pre- and post-repeal periods. State-wide surveys of helmet use involving observations of 12,228 cyclists in 1976 and 12,826 in 1977 showed statistically significant declines in rates of helmet use for all sub-sets of cyclists. The overall rate of driver helmet use declined from 99.6% in the pre-repeal period to 57.3% during the post-repeal period. Passenger helmet use declined from 99.3% to 60.7% between periods. Large decreases in helmet use were observed for all time-of-day and day-of-week periods, and for all roadway types. Although no detectable changes were observed in state-wide fatal, injury, or total crash rates, analyses of medical data for accident victims showed substantial evidence of negative impact of helmet law repeal. During the 24-month study period, head/skull injuries were recorded for 9.2% of helmeted riders compared to 21.1% of unhelmeted riders. Injury severity was also significantly greater for unhelmeted than for helmeted accident victims.

IMPACTS OF MOTORCYCLE HELMET LAW REPEAL IN SOUTH DAKOTA. APPENDICES. FINAL REPORT

Materials and data supplementary to Vol. 1 of the study on impacts of motorcycle helmet law repeal in S. Dak. are presented in 14 appendices. These include a description of sites and area maps for the sampling locations, S. Dak. police reports and a medical injury data report form, copies of letters requesting hospital participation and victims' consent forms, raw frequencies for the accident file, driver-vehicle file and rider file variables, and extensive supplementary tables.

AN INITIAL ASSESSMENT OF THE LITERATURE ON THE MEASUREMENT, CONTROL TRANSPORT, TRANSFORMATION AND HEALTH EFFECTS OF UNREGULATED DIESEL ENGINE EMISIONS. FINAL REPORT

An initial assessment is presented of the literature in critical areas related to the measurement, control, atmospheric processes, and possible health effects of unregulated diesel engine emissions, under four major topics: measurement and characterization of emissions; control technology; atmospheric transport, transformation and microbiological assay; and carcinogenic aspects. Primary emphasis is directed at particulate matter, with secondary emphasis on odor and gaseous phase organics. A separate bibliography follows each section.

IMPACT OF THE REPEAL OF THE KANSAS MANDATORY MOTORCYCLE HELMET LAW. FINAL REPORT

An evaluation was made of the effects of the repeal of the Kansas mandatory motorcycle helmet law (effective 1 Jul 1976), through a retrospective analysis of the incidence and severity of injuries to motor cyclists involved in accidents in pre- and post-repeal periods. In addition to collecting data on accidents and injuries occurring in 1975 and 1976, an observational survey was completed during 1977 to determine current usage of motorcycle helmets and/or eye protection. The overall usage of motorcycle was found to be 47.1%. while some form of eye protection was used by 70.2% of those observed. The data indicate that statistically significant increases in the incidence and severity of injuries to the head and to the general body occurred between the pre-repeal and post-repeal periods. Extremely significant increases were found for nonhelmeted vs. helmeted riders. The data also indicate that the crude death rate was significantly higher for nonhelmeted vs. helmeted motorcyclists.

SCHOOL BUS OCCUPANT RETROFIT PROTECTIVE MATERIALS. VOL. 2: FINAL TECHNICAL REPORT.

An investigation was made of the methods and materials that might be used to retrofit protective padding to older model school bus seats, modesty panels, and stanchions. Laboratory tests were designed to compare these bus components with and without protective padding. The tests were conducted under Federal Motor Vehicle Safety Standard (FMVSS) 222, School Bus Seating and Crash Protection, guidelines in an attempt to evaluate applicability to retrofitting. Impact tests were conducted on existing commercial retrofit padding and on candidate materials. It was determined that the dynamic portions of FMVSS 222 could be applied to the retrofitting of older model school buses. The seat back rail and the modesty panel were found to be the most dangerous objects in terms of potential facial injuries. It was found that the older model school bus seats do not present severe danger of concussion-type head injuries as defined by the Head Injury Criterion value of FMVSS 222. It is concluded that existing commercial paddings could be used to minimize facial-type injuries in accordance with FMVSS 222.

PROPOSED PLAN FOR HIGHWAY SAFETY RESEARCH, DEVELOPMENT AND DEMONSTRATION (SECTION 403 OF TITLE 23, USC) FISCAL YEARS 1980-1984

The Section 403 (of the Highway Safety Act of 1966) program priorities are described, along with supporting rationale, for fiscal years 1980 through 1984. Specific projects and associated funding are presented by year, as well as the program areas. Project area descriptions and resultant products are included. The proposed plan provides the U.S. highway safety community and general public with an opportunity to react and comment during the early stages of the 403 program planning process. The National Hwy. Traffic Safety Administration (NHTSA) is also seeking the expertise of the safety community by sponsoring a 403 Program Conference at the Dulles Marriott Hotel, Chantilly, Virginia, Apr 22-26, 1979, to be conducted by the Transportation Research Board (TRB) of the National Academy of Sciences. That organization will act as an independent and objective moderator for reactions to the 403 Program Plan, and will formally report the Conference results to NHTSA, the safety community, and the public by Aug 1979. The intention is to provide a neutral atmosphere for the integration of private, public, and government opinion for the purposes of molding a 403 highway safety plan which is responsive to state and community needs. The TRB Conference Report will assist NHTSA in its Section 403 planning, and along with comments to the docket, will form the basis for publication of an updated Section 403 plan in late 1979.

DEVELOPMENT OF VEHICLE ROLLOVER MANEUVER. VOL. 1. FINAL REPORT

Results are reported of research aimed at investigating the rollover response characteristics of automobiles. Emphasis was placed on the development of a test procedure to evaluate performance under untripped flat-surface operating conditions. Both simulation and full-scale experimental methods were employed to examine the effects of a variety of configurational and operational factors on rollover response. Over 500 test runs involving seven vehicles in ten configurations were performed. Studies were made of the effect of initial speed, steering input patterns, braking techiniques, suspension damping, loading, and tire characteristics. Testing was performed using both manual and automatic control methods. Appended are a review of the literature concerning rollover in actual accidents, analyses of the physics of tripped and flat surface (untripped) rollover, a discussion of the simulation study results, and an outline of a preliminary test procedure for vehicle rollover resistance evaluation. It was concluded that vehicle rollover response is dominated by the vehicle's rigid body geometry (with dynamic contributions from suspension effects) and that untripped rollover, even on highly skid-resistant surfaces, is difficult to predict and accomplish.

SIGNAL LIGHTING SYSTEM REQUIREMENTS FOR EMERGENCY, SCHOOL BUS AND SERVICE VEHICLES. FINAL REPORT

The inconsistency between various state laws and the Uniform Vehicle Code is reviewed regarding lighting systems for special vehicles and school buses. Accident data are cited that may have pertinent implications to the problem of lighting system design for these vehicles. Driver behavior problems are discussed that may be associated with the ambiguity of current signal messages, and an analysis is presented of the signal messages necessary to conduct particular vehicular missions. The review indicates that there is a diverse array of lighting devices available. Psychophysical visual and applied research was reviewed for information on the advantages and disadvantages of various coding parameters. An analysis of color, intensity, and flash rate summarized the information available that is applicable to special vehicle signaling systems. From this information was developed a set of recommended signals to transmit the messages deemed necessary for the efficient and safe control of various vehicular missions. These recommendations took into account current legal, stereotype, and changeover constraints. School bus signaling procedures were also reviewed and specific recommendations are made for new signals, usage procedures, legal language, and research.

FIVE YEAR PLAN FOR MOTOR VEHICLE SAFETY AND FUEL ECONOMY RULEMAKING, CALENDAR YEARS 1980-1984

The National Hwy. Traffic Safety Administration's (NHTSA) five yhear plan for motor vehicle safety and fuel economy updated from that of 16 Mar 1978 (43 F.R. 11100), is designed to provide policy guidance for use within NHTSA for the development and issuance of standards, to provide the public with information on proposed future activities and priorities, and to permit the motor vehicle industry to incorporate potential requirements in its long-range planning. The tentative rulemaking goals and priorities are briefly described and summarized, and public comments analyzed. Accomplishments since the draft publication are identified, as well as those areas where significant rulemaking is not expected to take place. A rulemaking schedule shows the anticipated dates for issuance of proposals and final rules and a rough estimate of the anticipated effective dates. Also included are those pending rulemaking actions which NHTSA contemplates terminating. Cross-referenced indexes cover changes since the Mar 1978 rulemaking plan, proposed safety rulemaking by vehicle type, and rulemaking by proposed effective date. An appendix describes in more detail the individual motor vehicle safety rulemaking actions, including a discussion of the safety problem that a regulation is designed to ameliorate, the approach to be used in developing and issuing the rule, and some of the major issues to be resolved in the development of the final rule.

RSV [RESEARCH SAFETY VEHICLE] PHASE 3. PROGRESS REPORT NO. 12, DECEMBER 1978-JANUARY 1979

Progress made on the Minicars RSV (Research Safety Vehicle) Phase 3 program is reported in task sections, summarized to the subtask level. Tasks include program management, product improvement of inflatable restraints, structural refinement, systems refinement, plastic material improvement, electronic system, ride and handling, pedestrian impact, compatability analysis, high-technology engine/transmission, structures and systems fabrication, accident/benefit analysis, and advanced engine. Tasks involving the Large Research Safety Vehicle (LRSV) include structure, restraints, design integration, testing, technology transfer support, and demonstration vehicle. Glazing, production planning, tooling, and pilot production are also reported. Appended are data traces for driver and passenger restraint system sled tests, for pulse development sled runs, and for 50 mph frontal impact test of RSV with a flat barrier. Also appended are subcontractor reports from RCA Labs. (electronics), Dubner Computer Systems, Inc. (analysis of high-technology transmission data), and Kinetic Res., Inc. (analysis of National Crash Severity data, comparison of vehicle population data used in the Kinetic Res. Accident Environment Simulation and Projection model with similar data projected by the Wharton Motor Vehicle Demand model).

FINAL ASSESSMENT OF THE BUMPER STANDARD

After examination of all available information from public comment, special orders to manufacturers, and crash tests, the costs and benefits were assessed of bumper technology used to comply with the Part 581 Bumper Standard issued in 1975. The analysis was made in three steps: various bumper systems and design speeds were defined; the costs and benefits were derived that accrue with each of ten bumper systems at each design speed decision; and totalled costs and benefits provided the net benefit for each bumper system at each design speed. Among the bumper systems considered are the unregulated (baseline) system, and steel, aluminum, and soft face bumpers (Phase I). A discussion of Phase II bumpers is appended. The first phase of the standard, effective 1 Sep 1978, requires that the vehicle, other than the bumper system, not be damaged in 5.0 mph front and rear barrier and pendulum impacts and 3 mph corner pendulum impacts. The second phase, effective 1 Sep 1979, limits the damage to the bumper itself. Included in the analysis are factors of obtainable costs and benefits, effect on insurance and legal fees, savings of consumer time and inconvenience, and considerations of health and safety. Further research is investigating reduction of injury to pedestrians by new urethane bumpers and front ends.

HS-804 719

FINAL ASSESSMENT OF THE BUMPER STANDARD. EXECUTIVE SUMMARY

A revised analysis is summarized of the comparative cost savings for car owners from the Federal 5.0 mph bumper standard and alternative 2.5 mph and 7.5 mph standards. A number of changes in the analysis and data from the initial 26 Feb 1979 report are summarized, focusing on steel bumpers; topics discussed are vehicle miles traveled/1978 dollars, prestandard damage/effectiveness of improved bumpers, bumper replacement costs, and insurance adjustment. The final assessment shows that 5.0 mph bumpers provide greater savings to the consumer than 2.5 mph bumpers. The Feb analysis showed that the net lifetime benefits of 2.5 mph bumpers were approximately $77 greater than the net benefits of 5.0 mph bumpers, sales-weighted by bumper type (steel, aluminum, soft face). The revised analysis shows that the 5.0 mph bumpers produce approximately $39 more in net benefits than the 2.5 mph bumpers. The net benefit is the present value of the expected savings resulting principally from damage avoided as a result of improved bumpers less the cost increases associated with the purchase and use of improved bumpers. The revised analysis also indicates that 7.5 mph bumpers produce marginally greater savings than 5.0 mph bumpers, although these results are far less reliable because of the many assumptions that were used in the 7.5 mph bumper analysis.

DPMAS [DRIVER PERFORMANCE MEASUREMENT AND ANALYSIS SYSTEM] UTILIZATION. VEHICLE PARAMETER IDENTIFICATION. FINAL SUMMARY REPORT.

By restricting the roll angle of the vehicle to small values, fourth order differential equations (which neglect the effects of wheel dynamics, vertical motion, and constrain vehicle motion so that wheels are always on the ground) are shown to be reduced to the classical bicycle model of vehicle motion. Not all of the coefficients in this second order model are measurable, but may be computed if the transfer function of the vehicle is known. Using the second order model, plus the well-known result from control theory which implies that the quasilinear behavior of most physical systems is well approximated by a linear second order differential equation with variable coefficients, a method has been demonstrated which makes possible the estimation of the transfer function coefficients for the second order model from data taken by the Driver Performance Measurement and Analysis System. A second method has been developed for estimating the bicycle model physical parameters, once the yaw rate to steer angle transfer function is known. It was observed that, if the second order model thus estimated gives a reasonable fit to the data, then a very simple measure, based on the damping ratio of the second order roots of the model, can be used to display a measure of relative vehicle stability which is a function of both speed and lateral acceleration.

PROPOSED PROGRAM IMPLEMENTATION PLAN FOR 55 MPH NONCOMPLIANCE AND OTHER UNSAFE DRIVING ACTS, FISCAL YEARS 1980 TO 1984, FOR HIGHWAY SAFETY RESEARCH,DEVELOPMENT, AND DEMONSTRATION UNDER SECTION 403 OF TITLE 23, USC

This plan addresses activities designed to identify, develop, and transfer to the states and to communities, those systems, technologies, guidelines, and information that will help them reduce violations of the 55 mph speed limit and certain other unsafe driving actions (UDA'S) causally associated with traffic accidents (e.g. following too closely, making unsafe entry into traffic flow, driving at unsafe speed for conditions). The highest priority and most of the overall effort called for in this plan are allocated to developing and testing procedures for improving compliance with the 55 mph speed limit. The highest priority programs proposed for development and test include police enforcement and related public information techniques, strategies, and programs designed to deter violations, to increase the risk of detection and apprehension for 55 mph violation, and to alert drivers to this increased apprehension risk; public information and education programs to inform the driving public of the safety and energy benefits of the 55 mph speed limit, thereby improving voluntary compliance; and programs for citizen reporting of individual violators or high violation areas to assist in deterring violations. The plan also covers the development of countermeasure procedures for selected UDA'S. Interface with police traffic services, traffic law adjudication, and driver license plans is anticipated when the results of research included in the plan become available.

PROPOSED PROGRAM IMPLEMENTATION PLAN FOR PEDESTRIAN/BICYCLIST/PUPIL TRANSPORTATION PROGRAM, FISCAL YEARS 1980 TO 1984, FOR HIGHWAY SAFETY RESEARCH, DEVELOPMENT, AND DEMONSTRATION UNDER SECTION 403 OF TITLE 23, USC

This plan addresses activities designed to identify, develop, and transfer to the states and to communities, those systems, technologies, guidelines, and information that will help them reduce urban and rural pedestrian accidents, bicycle/motor vehicle accidents, and school bus accidents. Problem identification for newly identified accident situations will receive priority effort. Countermeasures for second priority accident types will be developed and test and demonstration projects conducted. Previously implemented countermeasures will be evaluated. Passing on new developments and management and technical information to the states will be a prime activity. In the rural pedestrian area, major efforts will be devoted to countermeasure development, test, and demonstration. Activities in the area of bicycle/motor vehicle accidents will focus on countermeasure development, test, and demonstration and the transfer of research findings and information on state program efforts. In the area of pupil transportation, attention will be devoted to problem identification, and countermeasure development, test, and demonstration. Included in the plan is investigation of relevant parts of the Alcohol, Young Driver, and Driver Licensing Area Plans.

PROPOSED PROGRAM IMPLEMENTATION PLAN FOR STATE PROGRAM MANAGEMENT, FISCAL YEARS 1980 TO 1984, FOR HIGHWAY SAFETY RESEARCH, DEVELOPMENT, AND DEMONSTRATION UNDER SECTION 403 OF TITLE 23, USC

This plan addresses activities for improving the capabilities of state and local program management to implement the "process" approach for the state and community Highway Safety Program. The major objective guiding proposed program efforts is to provide the leadership, technical assistance, management procedures and tools, and training programs to states for carrying out efficient and effective highway safety operations. To facilitate the transition from the past "standards" or prescriptive approach to the process approach in safety management, priorities have been established under the following categories: data analysis and problem identification; planning and programming, including the steps and procedures necessary to develop a viable Highway Safety Plan; evaluation, including procedures, methodology, and criteria for conducting impact, administrative, and overall statewide evaluations; and manpower development and training for state, regional, and headquarters personnel. Activities in this program area will interface with most of the other plans, particularly the Traffic Records Plan.

PROPOSED PROGRAM IMPLEMENTATION PLAN FOR TRAFFIC LAW ADJUDICATION, FISCAL YEARS 1980 TO 1984, FOR HIGHWAY SAFETY RESEARCH, DEVELOPMENT, AND DEMONSTRATION UNDER SECTION 403 OF TITLE 23, USC

This plan addresses activities designed to improve the components of the traffic law system that deal with enforcement, adjudication, and sanctions. Efficiency of performance, fairness to motorists, and effectiveness in driver control are the objectives. Planned activities will address the following problems: the lack of education and training for prosecutors, judges, court clerks, and court administrators in the highway safety impact of their role in the traffic law system; the need to simplify and make more efficient the adjudication of minor traffic cases; and the unnecessary practice of immediate arraignment of nonresident traffic violators, which consumes a large amount of police time. The priorities are as follows: training of traffic adjudication professionals, promotion of the Nonresident Violator Compact, development of model information systems for traffic courts, packaging of existing materials on administrative adjudication for transfer to the states, and testing and demonstration of model traffic adjudication system. Activities in this program area relate to the Enforcement, Driver Licensing, Driver Education, and Alcohol Plans.

PROPOSED PROGRAM IMPLEMENTATION PLAN FOR POLICE TRAFFIC SERVICES, FISCAL YEARS 1980 TO 1984, FOR HIGHWAY SAFETY RESEARCH, DEVELOPMENT, AND DEMONSTRATION UNDER SECTION 403 OF TITLE 23, USC

This plan will help to provide effective guidance, and technical assistance to enforcement agencies in order to improve the efficiency and effectiveness of police traffic services and to increase the amount of police effort allocated to traffic services. The plan is designed to use the members of authoritative police organizations and nationally recognized police educational institutions to help identify problems for "product" development by the National Hwy. Traffic Safety Administration, to act as quality control for the product developed, and to help "market" the product or technology transfer within the police community. The necessary technical assistance will be solicited through workshops, advisory groups, and seminars. Police organizations to be used initially include the following units of the International Assoc. of Chiefs of Police: the Hwy. Safety Com., the State and Provincial Div., and the State Police Planning Officer's Section. Future efforts will include the National Sheriffs Assoc., the Traffic Inst. (Northwestern Univ.), and the Southern Police Inst.

PROPOSED PROGRAM IMPLEMENTATION PLAN FOR DRIVER LICENSING PROGRAM, FISCAL YEARS 1980 TO 1984, FOR HIGHWAY SAFETY RESEARCH, DEVELOPMENT, AND DEMONSTRATION UNDER SECTION 403 OF TITLE 23, USC

The Driver Licensing Plan (DLP) is designed to develop a modern, comprehensive driver control system that will upgrade the general level of driver performance in the U.S. and will contribute to a reduction of the incidence of highway traffic accidents involving unqualified and impaired drivers. The DLP fundamentally seeks to develop socially acceptable policies and procedures for use by the states in administering their driver licensing and driver improvement functions and in detecting and correcting deviant driver behavior. The results expected from research and from demonstration programs in driver licensing will help strengthen and modernize various licensing procedures, will improve postlicensing control and driver improvement activities, will promote more effective use of driver record and enforcement personnel, and will expedite the adjudication and disposition of traffic offenses. The following program c ponents are proposed to address major deficiencies in the dri licensing system: the "one-license, one-record" concept (addr es the problem of multiple licenses and records, provides proved driver identification and system security, and fills need for an updated and strengthened Driver License C pact), control of suspended or revoked (S/R) drivers (provi methods for control of S/R drivers through specific coun measure development, evaluation of "hardship" or "occupati al" licensing), technology transfer (provides prompt transfe driver licensing administrators such products as Traffic L Commentaries, improved driver screening materials, and be definition of regulatory problems and recommended solutic model comprehensive driver licensing system (development implementation), heavy-duty vehicle operators (development special tests, regulatory procedures, and driver improvem procedures), and medically impaired and elderly drivers (de opment of risk levels, along with medical criteria and match of driver disabilities to licensing restrictions, provision of gui lines for assisting elderly drivers in personally meeting and co pensating for medical problems).

PROPOSED PROGRAM IMPLEMENTATION PLA FOR NATIONAL DRIVER REGISTER, FISCAL YEARS 1980 TO 1984, FOR HIGHWAY SAFETY RESEARCH, DEVELOPMENT, AND DEMONSTRATION UNDER SECTION 403 OF TIT 23, USC

The National Driver Register (NDR) is designed to assist st in identifying and controlling problem drivers, thereby reduc accidents and the resultant injuries, fatalities, and prope damage. Concurrently with the continuing operation of NDR, the development of a replacement system with ra response capability that is responsive to expressed state need being pursued on a priority basis. It is planned to operate a p system in four states during FY 1981 for purposes of demons tion and evaluation. Upon favorable evaluation of the system is planned to phase four states into the system annually until users desiring rapid response capability are accommodat Other users would participate through the mails as before.

PROPOSED PROGRAM IMPLEMENTATION PLA FOR MOTORCYCLE AND MOPED PROGRAM, FISCAL YEARS 1980 TO 1984, FOR HIGHWAY SAFETY RESEARCH, DEVELOPMENT, AND DEMONSTRATION UNDER SECTION 403 OF TIT 23, USC

This plan addresses activities for improved motorcycle moped safety. The proposed program efforts are designed develop an internal planning document to guide National Hwy. Traffic Safety Administration (NHTSA) officials and program managers in preparing program strategies and necessary resource requirements, and to provide the public, private groups, and government at all levels with insight into NHTSA'S plans. The plan will permit these groups to comment during the early stages, and will permit the motorcycle and moped industry and appropriate government agencies to anticipate NHTSA actions in their own planning. The overall goal is to reduce motorcycle and moped accidents, injuries, and fatalities. The following program areas are given the highest priority: conspicuity, with emphasis on both rider and vehicle visibility; operator education and training, including both novice and experienced operators; operator licensing, including development of a complete licensing system; rider protection, with particular attention to helmet usage; and moped safety, involving program development to counter predicted safety problems inherent in increased moped use. Activities in this area are closely related to those of the Young Driver and Driver Licensing Plans.

PROPOSED PROGRAM IMPLEMENTATION PLAN FOR YOUNG DRIVER, FISCAL YEARS 1980 TO 1984, FOR HIGHWAY SAFETY RESEARCH, DEVELOPMENT, AND DEMONSTRATION UNDER SECTION 403 OF TITLE 23, USC

This plan addresses activities to reduce the vast number of young drivers involved in highway accidents. The two problem groups addressed are the novice driver (generally aged 16 to 19) and the young driver (aged 20 to 24). The scope of the planned efforts includes not only the licensing of young drivers at age 16 but also safety activities, particularly educational projects, directed at the younger, predriver groups. Although prevention (through driver education and licensing programs) is the primary area of emphasis, the detection and driver control functions of the police, courts, and rehabilitation agencies have an important role. Emphasis is also placed therefore on enforcement, adjudication, driver improvement, and sanction programs directed at the young driver. The overall goal is to prevent accident occurrence through teaching effective skills, providing traffic safety information, instilling safe-driving attitudes, and using improved licensing procedures, coupled with the general and specific deterring effects of appropriate enforcement, adjudication, and driver improvement and retraining programs. Activities in this plan interface with those in the alcohol, speeding motorcycle, safety belt, and safety support system plans.

PROPOSED PROGRAM IMPLEMENTATION PLAN FOR EMERGENCY MEDICAL SERVICES, FISCAL YEARS 1980 TO 1984, FOR HIGHWAY SAFETY RESEARCH, DEVELOPMENT, AND DEMONSTRATION UNDER SECTION 403 OF TITLE 23, USC

The Emergency Medical Services (EMS) Program is designed to ensure that victims of traffic accidents and medical emergencies receive prompt and adequate emergency care. This plan addresses activities for a comprehensive EMS system that includes emergency equipment, manpower, and facilities. The following specific traffic safety program goals are listed in priority order: to develop additional criteria for evaluating EMS system effectiveness and societal value, to formulate guidance for rural EMS development, to update and maintain EMS-RELATED training programs, to develop guidance for best use of the EMS system elements, and to assess and take advantage of available technological opportunities (both hardware and software) to reduce the cost and increase the effectiveness of the EMS system. Activities in this program area interface with those of the following individual implementation plans: Driver Licensing, Motor Vehicle Registration, Motor Vehicle Inspection, Police Traffic Services, Debris Hazard Control and Cleanup, Traffic Records, and Driver Education.

PROPOSED PROGRAM IMPLEMENTATION PLAN FOR OCCUPANT RESTRAINT USAGE, FISCAL YEARS 1980 TO 1984, FOR HIGHWAY SAFETY RESEARCH, DEVELOPMENT, AND DEMONSTRATION UNDER SECTION 403 OF TITLE 23, USC

This plan addresses activities to increase the number of people who use occupant restraints (active safety belts, air bags, automatic belts, child restraints) while traveling in motor vehicles. The five primary areas of activity are research, development, and pilot testing of various approaches for promoting restraint usage; education programs (including workshops) and materials distribution efforts; a coordinated mass media program; evaluation of education media, and legislative efforts; and assessment of restraint usage. The highest priority is program and countermeasure development, including workshops for advocacy groups and a coordinated mass media public information program. Secondary priority is given to program evaluation and evaluation support for state programs. Two other programming areas within the scope of Section 403 are the research and development of hardware by the Office of Passenger Vehicle Research, and the multidisciplinary accident investigation efforts involving occupant restraints by the National Center for Statistics and Analysis.

APPENDICES TO THE FIVE YEAR PLAN FOR MOTOR VEHICLE SAFETY AND FUEL ECONOMY RULEMAKING, CALENDAR YEARS 1980-1984

Except for fuel economy rulemaking, which was addressed in the main body of the plan, a detailed discussion is presented of the contemplated motor vehicle safety rulemaking activities included in the rulemaking plan. The appendices are presented in three sections in the order that they appear in the plan. Appendix A describes the near-term rulemaking, where information now available appears sufficient to justify Federal rulemaking activity. Appendix B describes the proposed technical amendments, minor rulemaking actions to clarify existing requirements or to resolve specific technical problems. Appendix C describes exploratory research and rulemaking activities, where there is obvious need for improvement but where precise solutions have not been developed or the role of Federal regulation has not been defined. Each rulemaking action is described by title, objective, applicability, safety problem, approach, and schedule (where appropriate).

WORKSHOPS ON TECHNOLOGICAL CHANGE IN THE U.S. AUTOMOBILE INDUSTRY, OCTOBER 1977 THROUGH APRIL 1978, AND SYMPOSIUM ON TECHNOLOGY, GOVERNMENT AND THE AUTOMOTIVE FUTURE, OCTOBER 19-20, 1978, PROCEEDINGS. FINAL REPORT

The purpose of five workshops and a final symposium held at Harvard Univ. during 1977 and 1978 was to explore the implications of technological change in the U.S. automotive industry in support of improved policy formulation to meet emerging national needs. The impetus for these changes originates mainly in direct government policy, but also in diminished energy resources, and international competition. The meetings were designed to gather insight and understanding from specialists who have intimate knowledge about problems and opportunities for improvement. A unique objective of this program has been to engage a broader range of participants than heretofore in a constructive effort to promote progress in a form consistent with national needs. The five workshops dealt with the motor vehicle regulatory process, the consumer and the supply industry as factors in motor vehicle innovation, changing incentives for motor vehicle research and development, and the role of national and multinational corporations in motor vehicle innovation. The five key issues emanating from these workshops were the Federal research and development policy in the motor vehicle sector, product rating information for consumers, regulatory decision-making, regulation and international trade, and transportation policy.

COLLISION AVOIDANCE RADAR BRAKING SYSTEMS INVESTIGATION - PHASE 3 STUDY. FINAL TECHNICAL REPORT

The final report is presented of the Phase III program to study the potential application of an anticipatory radar braking system in preventing motor vehicle accidents. The design of the experimental radar braking system by Bendix Res. Labs. is described, including the installation of the system on two test vehicles. A summary of the functional tests which demonstrate the performance of the experimental system is also included. The system description follows an introductory general discussion (section 1). Section 2 outlines the design of the radar sensor, including the signal processing electronics, control panel display, and installation of the entire subsystem on the test vehicles. Sections 3 and 4 describe the design of the brake actuation subsystem and the anti-lock subsystem, respectively, and include information about installation of these two subsystems on test vehicles. Section 5 outlines functional tests conducted with the two test vehicles equipped with the radar braking system which demonstrate system performance. In addition to general observations about closed-loop braking performance of the two radar-brake-equipped test vehicles, Section 6 outlines the major differences in performance between the two test vehicles. More extensive tests of the radar braking system installed in the test vehicles are recommended. A test plan, separate from this report, has been submitted.

COLLISION AVOIDANCE RADAR BRAKING SYSTEMS INVESTIGATION. PHASE 3 STUDY. FINAL REPORT

A prototype Collision Avoidance Radar Braking System was installed on two vehicles and limited performance testing was carried out; further testing under varying conditions is required. Test methodology is described: parameters such as system sensitivity, dynamic braking performance on curves, and performance in the presence of precipitation are recommended for testing in a controlled test-track environment and in highway driving. Test-track requirements and target profiles (both simulated and real) are described. Recommended test instrumentation is described and data collection procedures outlined, including order of testing, number of runs, recorder speed, correlation with visual observations, and speed and brake temperature measurement. The continued test program should cover approximately eight months; a schedule for specific tests is suggested.

VISUAL DETECTION OF DRIVING WHILE INTOXICATED. PROJECT INTERIM REPORT: IDENTIFICATION OF VISUAL CUES AND DEVELOPMENT OF DETECTION METHODS

The initial phase is described of a two-phase project designed to develop and test procedures for enhancing on-the-road detection of driving while intoxicated (DWI). The emphasis of the first phase was on the identification of visual cues and the development of procedures that effectively discriminate between DWI and driving while sober (DWS). The literature was reviewed, expert opinion was surveyed, 1288 DWI arrest reports were analyzed, and an on-the-road detection study was conducted in which trained observers accompanied police officers on patrol and recorded 643 instances of driving behavior and vehicle actions that deviated from normal. In each instance, the patrol officer stopped the vehicle and measured the blood alcohol concentration (BAC) of the driver with a portable breath tester. A DWI detection guide was developed to facilitate the application of research findings to the on-the-road detection of DWI by police patrol officers. The guide consists of 23 visual cues, a value for each cue reflecting the ability of the cue to discriminate between DWI and DWS, and a set of three rules for estimating the probability of DWI for any set of observed cues. The 23 cues accounted for 92 percent of the cues observed during the detection study. It was concluded that alcohol-induced driver impairment is exhibited mainly in steering and velocity control, time-sharing of attention, and information processing. Development of the detection guide was governed by the following criteria: to account for the largest number of detection events with the smallest number of detection cues; to enhance the discriminability of available cues; to employ a probabilistic output; to accommodate multiple-cue occurrences; to accommodate alternative enforcement statutes, policies, and strategies; and to emphasize simplicity, practicality, and ease of use. Prior to making the guide generally available or implementing its use on a wide scale, a field test is required to evaluate its effectiveness.

SMALL CAR DRIVER INFLATABLE RESTRAINT SYSTEM EVALUATION. VOL. 2: DRIVER AIR CUSHION RESTRAINT (ACRS) DEVELOPMENT FOR 1976 VEGA, VALIANT, AND CHEVETTE SUBCOMPACT VEHICLES. FINAL REPORT

Sled tests (76) and car crash tests (7) were conducted to evolve production driver restraint systems for three Government furnished vehicles: 1976 Vega, Valiant, and Chevette. The effort was successful in providing 30-mph barrier equivalent velocity driver protection for all three vehicles. Resulting injury measurements were well within the limits set by the FMVSS 208 injury criteria. Protection was provided without changing the compartment interior geometry (except for the space required by the knee restraints), the column angle, or the driver's normal seating position. Although in the initial investigations the GM ACRS wheel and bag assembly (inflator, bag, cover) had been selected, it was later found necessary to substitute several system components to bring the vehicle systems into compliance with FMVSS injury criteria. The GM bag was modified to 120% of its original volume and an inflator with a correspondingly increased gas output was used. The stock energy absorbing steering column units of the Vega and Chevette were found to be too sensitive to the bending moments created by vertical loads at the wheel rim and were thus replaced by the Minicars tube/mandrel collapsible steering column, a system which easily satisfies industry standard torque criteria for steering columns. To assure controlled column collapse, the original column support bracketry was strengthened and molybdenum-impregnated nylon runners were installed. The appendix includes Vega sled test measurements and car crash tests, Valiant and Chevette sled tests, Chevette car crash tests, and oblique impact simulation for the Chevette. le,

EXECUTIVE AND TABULAR SUMMARY OF AIR BAG FIELD EXPERIENCE. VOL. 3, NO. 1. FINAL REPORT

Narrative summaries and tables describe a total 57 accidents involving air bag equipped cars, which were reported to NHTSA from 1 Sep 1977 through 31 Aug 1978 (33 deployment cases and 24 nondeployment cases). The information was extracted from the NHTSA in-depth reports by accident investigation teams from five regional research stations. In each case the following data are included: date, location, DOT HS number, type of accident, year and make of other vehicle(s) involved, speed of impact, driver and passenger(s) information, their injury codes, damage to the vehicles, and damage codes.

LONG LIFE HYDRAULIC BRAKE SYSTEM. SUMMARY REPORT. FINAL REPORT

An analytical and experimental program was conducted t design a long life brake system for passenger vehicles whic would double the period between required servicing of conver tional systems. The design approach was to be compatible wit existing vehicle configurations and not to differ radically i braking principle. Formal objectives were: to analyze the stat of-the-art hydraulic brake systems, identifying system assembl and/or component design requirements which will assure a si nificant increase in service life without maintenance or repair and which will not affect safety, performance, or fuel econom to develop techniques which can be utilized objectively in qua tifying system durability and recommend procedures suitable f use in compliance testing. Service life was found initially to be defined by friction pair maintenance in the 30,000 to 40,000 mile range. Subsequent servicing requirements were necessitated by a number of mechanisms derived in large part from fluid degradation, metal corrosion, and rubber deterioration. A long life design approach was specified satisfying a doubled friction pair lifetime and a 100,000 mile balance of system service-free life. Component-by-component design approach alternatives were given and three test procedures described with which to evaluate compliance with the postulated standard: brake fluid specification modification, system isolation/cycling test, and dynamometer wear cycle. Benefit-cost analysis demonstrated that the benefits of reduced accidents and consumer maintenance outweigh the costs.

CONSUMER SAFETY INFORMATION AS A GOVERNMENT POLICY TOOL

The influence of safety information on the consumer's automobile purchase decision is discussed, with particular reference to the National Hwy. Traffic Safety Administration's (NHTSA) consumer information program as authorized by Title II of the Motor Vehicle Information and Cost Savings Act of 1972. This Act authorized NHTSA to rate the comparative performance of automobiles with respect to crashworthiness, damageability, and ease of maintenance, and to provide information on each of these factors to the public. Extensive studies conducted since the Act was implemented indicate that consumers say that they are concerned about vehicle safety, but that the vast majority assume that all cars within a size class are equally safe. A Dept. of Transportation-sponsored survey found that the public's understanding of technological alternatives that can improve safety is deep, and its desire for additional information strong, although to date the public has had little access to information about car differences. In view of the decreases in sales of Ford Pintos, Firestone 500 tires, and Chrysler's Omni/Horizon after national publicity about their safety problems, it is clear that consumers act upon safety information when it is provided. Manufactureres respond to this consumer behavior in their advertising. The government disseminates consumer information in order to have consumers react in the marketplace to safety differences and to encourage companies to respond to consumers' desire for safety by upgrading products. The question that remains to be answered is whether consumer information based on qualitative ratings of the relative crashworthiness of cars creates the same reaction as well-publicized, life-threatening situations. This is a question NHTSA hopes to answer in developing its automotive ratings program.

REGULATION AND INNOVATION IN THE AUTOMOBILE INDUSTRY

At least six forces influence the rate of auto industry innovation as well as its focus, often interacting: internal stimulus; market structure; inventions; independent research; public expectations or crises; and government regulation. Since the 1930's, innovations in the auto industry have chiefly been those that benefit the manufacturer rather than the purchaser. Large auto companies tend to rely for advances in technology on their suppliers, whose research and development is rigidly constrained by the priorities of the giant manufacturers. The Office of Management and Budget urges Federal support of small business through the contracting and procurement process. Firms with less than 1,000 employees accounted for almost 1/2 of major U.S. innovations during 1953-73. Product competition based on technological advances has been abandoned by manufacturers in favor of the model year change, based on styling, and dealer-franchising policies--disincentives to innovation. Health and safety developments may be repressed by industry opposition, and inventions of safety and emission equipment shelved. Research by independent organizations and Government stimulates innovation by identifying critical problems and developing new concepts or hardware. Experimental safety vehicle program work was unsuccessfully attempted by domestic industry, yet satisfactory safety vehicles were produced through foreign industry. DOT is working on two new vehicles, small in weight, high in fuel economy, and with 40 to 50 mph crash survivability characteristics. The Insurance Institute for Highway Safety has played a major role in reducing vehicle damageability, developing an independent data system based on insurance industry information, and seeking the recall of defective vehicles. Consumer expectations have focussed in the past decade on safety and fuel economy. Future trends may be affected by the current overall reduction in the commitment of resources to civilian research and development, both in industry and government. High inflation and interest rates discourage investment in long-term research projects, but safety, conservation, health, and environmental regulatory programs contribute to control of inflation.

PROPOSED PROGRAM IMPLEMENTATION PLAN FOR MOTORCYCLE AND MOPED PROGRAM, FISCAL YEARS 1980 TO 1984, FOR HIGHWAY SAFETY RESEARCH, DEVELOPMENT, AND DEMONSTRATION UNDER SECTION 403 OF TITLE 23, USC
HS-804 755

PROPOSED PROGRAM IMPLEMENTATION PLAN FOR NATIONAL DRIVER REGISTER, FISCAL YEARS 1980 TO 1984, FOR HIGHWAY SAFETY RESEARCH, DEVELOPMENT, AND DEMONSTRATION UNDER SECTION 403 OF TITLE 23, USC
HS-804 754

PROPOSED PROGRAM IMPLEMENTATION PLAN FOR OCCUPANT RESTRAINT USAGE, FISCAL YEARS 1980 TO 1984, FOR HIGHWAY SAFETY RESEARCH, DEVELOPMENT, AND DEMONSTRATION UNDER SECTION 403 OF TITLE 23, USC
HS-804 758

PROPOSED PROGRAM IMPLEMENTATION PLAN FOR PEDESTRIAN/BICYCLIST/PUPIL TRANSPORTATION PROGRAM, FISCAL YEARS 1980 TO 1984, FOR HIGHWAY SAFETY RESEARCH, DEVELOPMENT, AND DEMONSTRATION UNDER SECTION 403 OF TITLE 23, USC
HS-804 749

PROPOSED PROGRAM IMPLEMENTATION PLAN FOR POLICE TRAFFIC SERVICES, FISCAL YEARS 1980 TO 1984, FOR HIGHWAY SAFETY RESEARCH, DEVELOPMENT, AND DEMONSTRATION UNDER SECTION 403 OF TITLE 23, USC
HS-804 752

PROPOSED PROGRAM IMPLEMENTATION PLAN FOR STATE PROGRAM MANAGEMENT, FISCAL YEARS 1980 TO 1984, FOR HIGHWAY SAFETY RESEARCH, DEVELOPMENT, AND DEMONSTRATION UNDER SECTION 403 OF TITLE 23, USC
HS-804 750

PROPOSED PROGRAM IMPLEMENTATION PLAN FOR TRAFFIC LAW ADJUDICATION, FISCAL YEARS 1980 TO 1984, FOR HIGHWAY SAFETY RESEARCH, DEVELOPMENT, AND DEMONSTRATION UNDER SECTION 403 OF TITLE 23, USC
HS-804 751

PROPOSED PROGRAM IMPLEMENTATION PLAN FOR YOUNG DRIVER, FISCAL YEARS 1980 TO 1984, FOR HIGHWAY SAFETY RESEARCH, DEVELOPMENT, AND DEMONSTRATION UNDER SECTION 403 OF TITLE 23, USC
HS-804 756

PROPOSED PROGRAM IMPLEMENTATION PLAN FOR 55 MPH NONCOMPLIANCE AND OTHER UNSAFE DRIVING ACTS, FISCAL YEARS 1980 TO 1984, FOR HIGHWAY SAFETY RESEARCH,DEVELOPMENT, AND DEMONSTRATION UNDER SECTION 403 OF TITLE 23, USC
HS-804 748

FIXED

SIMPLIFIED AIDS FOR TRANSPORTATION ANALYSIS. ESTIMATING ANNUAL RIDERSHIP AND OPERATING EXPENSE FOR FIXED ROUTE BUS SYSTEMS IN SMALL URBAN AREAS. FINAL REPORT
HS-026 348

FLAMMABLE

NEW HITCH HARDWARE LEGISLATED TO REDUCE DOUBLES ROLL, JACKKNIFE [TRANSPORT OF FLAMMABLE LIQUIDS IN DOUBLE TANK TRAILERS]
HS-026 338

FLAT

RUN-FLAT TIRE USES DOUBLE BEAD, REINFORCED SIDEWALL
HS-026 312

FLOW

ESTIMATING THE INFLUENCE OF PULSATING FLOW CONDITIONS ON THE PERFORMANCE OF A TURBINE
HS-026 363

TRAFFIC FLOW EVALUATION OF PAVEMENT INSET LIGHTS FOR USE DURING FOG. FINAL REPORT
HS-026 341

TURBOCHARGER COMPRESSOR PERFORMANCE EVALUATION AND CRITICAL FLOW FIELD MEASUREMENTS
HS-026 356

FLUID

FLUID CONDUCTORS AND CONNECTORS. STANDARDS, RECOMMENDED PRACTICES, INFORMATION REPORT. HANDBOOK SUPPLEMENT. 1979 ED.
HS-026 333

SILICONE BRAKE FLUID: ANSWER TO CORROSION
HS-026 084

FLUIDS

BRIDGING THE GAP BETWEEN DEXTRON-II AND TYPE F ATF [AUTOMATIC TRANSMISSION FLUIDS]
HS-026 285

FOG
TRAFFIC FLOW EVALUATION OF PAVEMENT INSET LIGHTS FOR USE DURING FOG. FINAL REPORT
HS-026 341

FOLLOWER
"SAFE-APPROACH" VEHICLE-FOLLOWER CONTROL
HS-026 383

FRICTION
FRICTION MODIFIERS TAILOR BRAKE AND CLUTCH CHARACTERISTICS
HS-026 309

FRINGE
SIMPLIFIED AIDS FOR TRANSPORTATION ANALYSIS. ESTIMATING FRINGE PARKING SITE REQUIREMENTS. FINAL REPORT
HS-026 351

FRONT
FRONT DRIVE SYSTEMS FOR FOUR-WHEEL DRIVE LIGHT TRUCKS
HS-026 114

FUEL
AERODYNAMIC DESIGN BOOSTS FUEL ECONOMY AND ROOMINESS
HS-026 305

APPENDICES TO THE FIVE YEAR PLAN FOR MOTOR VEHICLE SAFETY AND FUEL ECONOMY RULEMAKING, CALENDAR YEARS 1980-1984

THE UNITED KINGDOM AUTOMOBILE INSURANCE MARKET. FINAL REPORT
HS-804 151

KRAFTFAHRER

DRIVER IMPROVEMENT--IMPROVEMENT OF DRIVING BEHAVIOR OF PARTICULAR MOTOR VEHICLE DRIVERS. EXPERIENCE AND THEORETICAL CONSIDERATIONS (DRIVER IMPROVEMENT--VERBESSERUNG DES VERKEHRSVERHALTENS AUFFALLIGER KRAFTFAHRER. BISHERIGE ERFAHRUNGEN AND THEORETICSCHE GRUNDLAGEN)
HS-026 103

LABOUR

LABOUR-SAVING METHODS FOR COUNTING TRAFFIC MOVEMENTS AT THREE-AND FOUR-ARM JUNCTIONS
HS-026 302

LAW

IMPACT OF THE REPEAL OF THE KANSAS MANDATORY MOTORCYCLE HELMET LAW. FINAL REPORT
HS-804 018

IMPACTS OF MOTORCYCLE HELMET LAW REPEAL IN SOUTH DAKOTA: EXECUTIVE SUMMARY. FINAL REPORT.
HS-803 960

IMPACTS OF MOTORCYCLE HELMET LAW REPEAL IN SOUTH DAKOTA. VOL. 1. FINAL REPORT
HS-803 996

IMPACTS OF MOTORCYCLE HELMET LAW REPEAL IN SOUTH DAKOTA. APPENDICES. FINAL REPORT
HS-803 997

PROPOSED PROGRAM IMPLEMENTATION PLAN FOR TRAFFIC LAW ADJUDICATION, FISCAL YEARS 1980 TO 1984, FOR HIGHWAY SAFETY RESEARCH, DEVELOPMENT, AND DEMONSTRATION UNDER SECTION 403 OF TITLE 23, USC
HS-804 751

LAWS

HELMET LAWS DWINDLE: DEATH TOLL MOUNT [MOTORCYCLING]
HS-026 324

LEGAL

MOTORCYCLE HELMET USE IN RELATION TO LEGAL REQUIREMENTS
HS-026 104

LEGIBILITY

THE NIGHTTIME LEGIBILITY OF HIGHWAY SIGNS AS A FUNCTION OF THEIR LUMINANCE CHARACTERISTICS
HS-026 079

LEGISLATED

NEW HITCH HARDWARE LEGISLATED TO REDUCE DOUBLES ROLL, JACKKNIFE [TRANSPORT OF FLAMMABLE LIQUIDS IN DOUBLE TANK TRAILERS]
HS-026 338

LEMON

LEMON AID [ADVICE ON BUYING A USED CAR]
HS-026 299

LET

LET'S REFRESH ON ALIGNMENT: 'CONSUMERS' VS. 'CROOKS' [WHEEL ALIGNMENT PRINCIPLES]
HS-026 105

LIABILITY

PRODUCT LIABILITY AND THE MOTORCYCLE DESIGNER
HS-026 292

LICENSE

PIERCING THE DRIVER LICENSE VEIL [NON-USE OR MISUSE OF THE NATIONAL DRIVER REGISTER IN ISSUING LICENSES]
HS-026 368

WHY NOT USE DRIVER LICENSE EXAM TO SCREEN FOR HEALTH PROBLEMS?
HS-026 108

LICENSES

PIERCING THE DRIVER LICENSE VEIL [NON-USE OR MISUSE OF THE NATIONAL DRIVER REGISTER IN ISSUING LICENSES]
HS-026 368

LICENSING

ENOUGH OF YAWNING EXAMINERS AND PARALLEL PARKING [DRIVER LICENSING TEST]
HS-026 319

PROPOSED PROGRAM IMPLEMENTATION PLAN FOR DRIVER LICENSING PROGRAM, FISCAL YEARS 1980 TO 1984, FOR HIGHWAY SAFETY RESEARCH, DEVELOPMENT, AND DEMONSTRATION UNDER SECTION 403 OF TITLE 23, USC
HS-804 753

LIFE

LONG LIFE HYDRAULIC BRAKE SYSTEM. SUMMARY REPORT. FINAL REPORT
HS-805 068

LIGHT

EXHAUST EMISSIONS FROM A EUROPEAN LIGHT DUTY TURBOCHARGED DIESEL
HS-026 357

FRONT DRIVE SYSTEMS FOR FOUR-WHEEL DRIVE LIGHT TRUCKS
HS-026 114

LIGHTED

APPRAISALS OF VISIBILITY ON LIGHTED DRY AND WET ROADS
HS-026 377

LIGHTING

LIGHTING EQUIPMENT AND PHOTOMETRIC TESTS. STANDARDS, RECOMMENDED PRACTICES, INFORMATION REPORTS. HANDBOOK SUPPLEMENT. 1979 ED.
HS-026 339

SIGNAL LIGHTING SYSTEM REQUIREMENTS FOR EMERGENCY, SCHOOL BUS AND SERVICE VEHICLES. FINAL REPORT
HS-804 095

LIGHTS

TRAFFIC FLOW EVALUATION OF PAVEMENT INSET LIGHTS FOR USE DURING FOG. FINAL REPORT
HS-026 341

LIMIT

ASSESSING THE NATIONAL 55 M.P.H. SPEED LIMIT
HS-026 387

LIMITED

A LIMITED EVALUATION OF REFLECTIVE AND NON-REFLECTIVE BACKGROUND FOR OVERHEAD SIGNS. FINAL REPORT
HS-026 321

LINKS

SHORT-TERM PHASE STABILITY OF AUDIO SIGNALS IN MOBILE RADIO VEHICLE-BASE LINKS
HS-026 316

LIQUIDS

NEW HITCH HARDWARE LEGISLATED TO REDUCE DOUBLES ROLL, JACKKNIFE [TRANSPORT OF FLAMMABLE LIQUIDS IN DOUBLE TANK TRAILERS]
HS-026 338

LITERATURE

AN INITIAL ASSESSMENT OF THE LITERATURE ON THE MEASUREMENT, CONTROL TRANSPORT, TRANSFORMATION AND HEALTH EFFECTS OF UNREGULATED DIESEL ENGINE EMISIONS. FINAL REPORT
HS-804 010

STATUS OF THE AUTOMOTIVE SUPPLY INDUSTRY: A REVIEW OF INDUSTRY TRENDS FROM THE TRADE LITERATURE
HS-027 370

LITTLE

THE CRASHER PAPERS: NOTES FROM THE DROP ZONE. SOMETIMES A LITTLE HURT CAN HELP [MOTORCYCLE ACCIDENT STATISTICS]
HS-026 099

LIVES

MINNESOTA TELLS PUBLIC: "REAL PROS DRIVE 55...SAVES GAS! SAVES LIVES"
HS-026 107

LOCKING

BRAKING AND LOCKING CHARACTERISTICS OF VARIOUS TYPES OF MOTORCYCLE BRAKE SYSTEMS (BREMS- UND BLOCKIERVERHALTEN VON MOTORRADERN MIT VERSCHIEDENEN BREMSSYSTEMEN)
HS-026 325

LONG

LONG LIFE HYDRAULIC BRAKE SYSTEM. SUMMARY REPORT. FINAL REPORT
HS-805 068

LOOP

CLOSING THE LOOP [ELECTRONIC EMISSION CONTROL SYSTEM]
HS-026 373

LUBRICANT

PERFORMANCE EVALUATION OF A VERSATILE TWO-CYCLE LUBRICANT ADDITIVE
HS-026 118

LUMINANCE

THE NIGHTTIME LEGIBILITY OF HIGHWAY SIGNS AS A FUNCTION OF THEIR LUMINANCE CHARACTERISTICS
HS-026 079

MAIN
EFFECT OF MAIN FACTORS ON DYNAMIC PROPERTIES OF MOTORCYCLE TIRES
HS-026 288

MANAGEMENT
PROPOSED PROGRAM IMPLEMENTATION PLAN FOR STATE PROGRAM MANAGEMENT, FISCAL YEARS 1980 TO 1984, FOR HIGHWAY SAFETY RESEARCH, DEVELOPMENT, AND DEMONSTRATION UNDER SECTION 403 OF TITLE 23, USC
HS-804 750

MANDATED
MANDATED FUEL ECONOMY STANDARDS AS A STRATEGY FOR IMPROVING MOTOR VEHICLE FUEL ECONOMY
HS-027 364

MANDATORY
IMPACT OF THE REPEAL OF THE KANSAS MANDATORY MOTORCYCLE HELMET LAW. FINAL REPORT
HS-804 018

MANEUVER
DEVELOPMENT OF VEHICLE ROLLOVER MANEUVER. VOL. 1. FINAL REPORT
HS-804 093

MANUAL
CRASH VICTIM EXTRICATION TRAINING COURSE. EMERGENCY MEDICAL TECHNICIAN. STUDENT'S MANUAL. REV. ED.

Highway Safety Literature

U.S. Department of Transportation **National Highway Traffic Safety Administration**

TD 8.10:

NOTICE

Highway Safety Literature is a monthly publication of the National Highway Traffic Safety Administration (NHTSA). It is divided into the following sections: Abstract Citations, containing bibliographical information and abstracts; and an Index to Abstracts, including a keyword-out-of-context (KWOC) list of words in the title, followed by the full title and HS number (our accession number); an Author Index; a Corporate Author Index; a Contract Number Index; and a Report Number Index. In those months when information on contracts recently awarded is available, a section entitled Contracts Awarded is added at the back.

Abstracts appearing in **Highway Safety Literature** represent documents acquired by the Technical Reference Division, NHTSA. Documents related to the mission of NHTSA may be sent to the Editor at the address below for inclusion in the collection and abstracting in this publication. Please indicate availability source and price for each document.

Note: Publication of articles or abstracts in Highway Safety Literature is intended only for information. Views expressed are those of the authors and not necessarily those of the Administration. Reference to brand names, equipment, models or companies does not imply endorsement by NHTSA or the U.S. Department of Transportation.

Comments on the articles appearing in **Highway Safety Literature** may be addressed to

Editor

Technical Reference Division
National Highway Traffic Safety Administration
400 7th St. SW
Washington, D.C. 20590

AVAILABILITY OF DOCUMENTS

Documents listed in *Highway Safety Literature* are not available from the National Highway Traffic Safety Administration unless so specified. They must be ordered from the sources indicated on the citations, usually at cost. Ordering information for the most common sources is given below.

NTIS: National Technical Information Service, Springfield, Va. 22161. **Order by title and accession number: PB, AD, or HS.** When no PB number is given for NHTSA Technical Reports, order by prefacing the HS number with DOT, i.e. DOT-HS-000 000.

GPO: Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. **Give corporate author, title, personal author, and catalog or stock number.**

Reference copy only: Documents may be examined at the NHTSA Technical Reference Division or borrowed on inter-library loan through your local library.

See publication: Articles in journals, papers in proceedings, or chapters in books are found in the publication cited. These publications may be in libraries or purchased from publishers or dealers.

SAE: Society of Automotive Engineers, Dept. HSL, 400 Commonwealth Drive, Warrendale, Pa. 15096. Order by title and SAE report number.

TRB: Transportation Research Board, National Academy of Sciences, 2101 Constitution Ave., N.W., Washington, D.C. 20418.

Corporate author: Inquiries should be addressed to the organization listed in the individual citation.

ABSTRACT CITATIONS

SAMPLE ENTRIES

FORMAT OF ENTRIES IN HIGHWAY SAFETY LITERATURE

NHTSA accession number	HS-013 124
Title of document	**MAXIMUM BRAKE PEDAL FORCES PRODUCED BY MALE AND FEMALE DRIVERS**
Abstract	The object of this research was to obtain data concerning the maximum amount of brake pedal force that automobile drivers were able to sustain over a period of ten seconds. Subjects were told to apply the brakes in the test car as they would in a panic stop, and to exert as much force as possible on the pedal over the entire ten second test period. A total of 84 subjects were tested, including 42 males and 42 females. The results indicated that there is a wide distribution of values which characterizes the pedal force that the subjects were able to generate. Male subjects produced generally higher forces than did females. Over half the women tested were unable to exert more than 150 lbs. of force with either foot alone, but when both feet were applied to the pedal, force levels rose significantly.

NHTSA accession number	HS-018 924
Title of document	**NATURAL FREQUENCIES OF THE BIAS TIRE**
Abstract	The lowest natural frequencies of a bias tire under inflation pressure are deduced by assuming the bias tire as a composite structure of a bias-laminated, toroidal membrane shell and rigorously taking three displacement components into consideration. The point collocation method is used to solve a derived system of differential equations with variable coefficients. It is found that the lowest natural frequencies calculated for two kinds of bias tire agree well with the corresponding experimental results in a wide range of inflation pressures. Results of the approximate analysis show that the influences of the in-plane inertia forces on natural frequency may be considered small, but the influences of in-plane displacements are large, particularly on the natural frequency of the tire under low inflation pressure.

CONTINUOUSLY VARIABLE TRANSMISSIONS FOR CARS WITH HIGH RATIO COVERAGE

A review is presented of car transmission types and transmission requirements (especially for fuel savings), as well as a discussion of the potential advantages of continuously variable transmissions (CVT's) to provide low engine rpm with high vehicle speed. The control of the engine-clutch-CVT system to provide optimum performance is explained. Results of computer simulation and/or bench or road tests are provided for three transmissions: Renault hydrostatic prototype, 2-mode hydromechanical, and a Van Doorne prototype Transmatic. These tests, conducted as part of three current Renault projects, have demonstrated advantages for CVT's with high ratio coverage and high overdrive ratios; for cars equipped with spark ignition (SI) engines the advantages include smoother ride, improved fuel economy, and less noise, due to increased load levels but lower rpm. Highway fuel economy trends are quantified for diesel and/or turbocharged engines. Emission tests are in progress.

PURELY HYDROSTATIC HIGH RATIO TRANSMISSION

A prototype, purely hydrostatic, continuously variable transmission has been developed for passenger car applications, featuring high-power-to-weight-ratio hydraulic pump and motors to avoid bulk and weight penalties. Materials and manufacturing processes are no more sophisticated than for conventional automobiles. The transmission is capable of transferring 45 hp through an overall ratio of four, increased by 50% toward longer ratios at constant speed output and with shorter ratios at constant torque for start-up. The transmission could transfer up to 90 hp in a smaller range of ratios. Transmission geometry is suitable for installation in the present Renault 12 chassis (a front-wheel drive car with an engine delivering 45 hp at 5200 rpm, whose torque curve at maximum injection passes through a maximum of 9.2 mdaN at about 3500 rpm and through 6.3 mdaN at maximum speed). The calculated energy efficiency remains between 80% and 85% within a sufficiently wide operating range, even in the long ratios, but the actual efficiency seems to be 5% less in the useful operating range. Remaining work includes evaluating the actual efficiency in bench tests throughout the range, durability in vehicle use, noise, thermal balance in a vehicle, and retention of performance over time.

FABRICATION AND ASSEMBLY OF A GRAPHITE FIBER REINFORCED PLASTIC VEHICLE

The procedures used to fabricate and assemble a lightweight demonstration passenger car using graphite fiber reinforced plastic (G.F.R.P.) are described. The requirements of the unique vehicle made it necessary to combine state-of-the-art aerospace manufacturing methods (Vought Corp.) with current automotive prototype technology (Milford Fabricating Co.). The medium and small G.F.R.P. component groups consisting of fenders, bumpers, doors, decklid, package tray, wheels, dash, and cowl were produced for subassembly, body assembly, and final vehicle completion at the Milford Fabricating Co. Adhesives for assembly were tested and recommended by the Budd Co. Plastic Res. and Devel. Center (Hysol epoxy, Goodyear urethane). Ford Motor Co. supplied a 1979 prototype sheet metal body, prepreg graphite materials, the necessary engineering drawings, tooling aids normally supplied for the manufacture of sheet metal detail prototype parts, and one of the early production 1979 Ford LTD's, which was used as a source of parts. Major areas of the program are discussed in detail: master tooling aid development, high-temperature epoxy molds, component fabrication, component group subassembly, and assembly of body, chassis, and final vehicle.

MOPED, MINIBIKE, AND MOTORCYCLE ACCIDENTS. ASSOCIATED INJURY PROBLEMS

Data were analyzed for all police-reported motorcycle (473) and minibike (14) accidents that occurred in three contiguous counties in upstate New York (Monroe (Rochester), Wayne, and Ontario) from 1 Apr to 31 Dec 1976, as part of a program to improve safety and injury protection of riders of motorcycles, minibikes, and mopeds. About three-fourths of all riders were known to be injured; some data show that the injury rate was closer to 90%. The overall AIS (Abbreviated Injury Scale) for all riders was 1.34, which is about twice that sustained by occupants of closed vehicles in which a towaway criterion was used to sample overall accidents. Passengers fared somewhat better than operators (1.22 vs. 1.37). The average severity of an individual injury was 1.6. The most vulnerable body regions were the head, chest, and abdomen, with average severity of injuries of 2.8, 2.57, and 2.85, respectively; these accounted for 14.3% of all injuries. Overall, upper- and lower-extremity injuries accounted for 60% of all injuries. Head injuries accounted for only 5.5% of the injuries, the low figure attributed to helmet use. Skin injuries were the most frequent, while skeletal injuries comprised a substantial percentage (22.3%). Of 17 cyclists who were in critical and maximum severity accidents, 7 would have sustained severe head injuries regardless of helmet use, while in four out of six cases helmets attenuated head injuries (helmet failed in one case, was not a factor in the other); there were also two cases in which a helmet would have attenuated injury and two cases with no head contact. The highest AIS occurred in head-on collisions between motorcycles and other vehicles (AIS of about 2.5, accounting for 3.1% of all injuries). The overall average severity of injuries in motorcycle-only accidents was 1.42. The severity of injuries sustained by minibike operators and passengers was comparable to that of motorcycle riders.

EVALUATION OF HIGHWAY ADVISORY RADIO IN THE I-35W TRAFFIC MANAGEMENT NETWORK. FINAL REPORT

A project was initiated in Dec 1977 on a segment of I-35W between I-494 and 66th St. in Richfield, Minnesota as part of the Minnesota Dept. of Transportation's I-35W traffic management system, in order to obtain installation, operations, maintenance, and evaluation data on highway advisory radio (HAR) in a surveillance and control network. The installation and operations of HAR for a one-year period are described and assessed, including analyses of major system elements, message characteristics, motorist use and acceptance, and various system costs. It is concluded that the HAR system is an effective element of the I-35W traffic management program. Motorist awareness and use of the system were satisfactory. Traffic diversion studies indicated that commuters divert from the freeway in response to an HAR broadcast when congestion is heavy, when they are given sufficient detailed information, and when they have adequate alternate routes. Motorist acceptance of the system was very high. System limitations included the fact that 20% of the commuters never tuned to HAR broadcasts, another 17% had serious tuning difficulties, 3% were not aware of the system, and 3% had no AM radio in their car. These limitations could largely be overcome by expanding the system, upgrading the broadcast quality, and providing more detailed traffic information. System implementation and operation did not place a great demand on financial and staff resources.

EASY RIDER--HARD FACTS: MOTORCYCLE HELMET LAWS

Various statistics and studies are cited to show the extent of the fatal motorcycle accident problem and the vulnerability of the unprotected head of the motorcyclist who does not wear a helmet. Responses are enumerated from a 1977 American Medical Association (AMA) conference to common motorcyclist allegations. The AMA opinions indicate that helmets per se do not contribute to or worsen cervical-spine injuries; that helmets provide only minor restrictions in peripheral vision; that hearing reduction associated with helmet use is inconsequential in a driving situation; and that no evidence supports helmet weight as a cause of accidents and increased rider fatigue. The unsuccessful challenge to the constitutionality of motorcycle helmet use laws in the courts is mentioned, and results of various studies are cited which show the decline in motorcycle accident fatalities after implementation of mandatory helmet use laws, and an increase after repeal. Considerable support is claimed for mandatory helmet laws (one study reporting 55% and 92% acceptance of such laws by motorcyclists and the general public, respectively). The Massachusetts Dept. of Public Health strongly supports the following recommendations of the AMA's Conference on Head Protection for the Cyclist: that everyone who drives or rides a motorcycle wear a properly fitted, approved helmet; that full-facial-coverage be provided; and that the medical and public health community actively involve itself in promoting the use of safety helmets. The Department also supports medical community cooperation with the Dept. of Transportation's efforts to persuade the motorcycle industry to emphasize the utilitarian aspects of moderate-performance vehicles rather than to push sales of overpowered machines.

FOCUS ON FASTENERS. THE CHANGING WORLD OF NUTS, BOLTS, ADHESIVES AND WELDING

Downsizing and weight reduction, the switch to metrication, the trend toward more corrosion-resistant materials and coatings, and concerns over defects and liability litigation are creating changes in fasteners (screws, nuts, bolts) and other joining systems, such as welds and adhesives. As cars get smaller and lighter so do the fasteners that hold subassemblies together. To reduce causes of corrosion, many holes in car bodies formerly used for fasteners are being eliminated. Metal clips are being replaced by plastic in external trim applications. Growing plastic usage in body components is requiring new designs to accommodate the material changes. Increasing use of aluminum in body panels is expanding use of hemming and stitching techniques to replace resistance spot welding in order to cut costs and energy use and to boost productivity. High strength steel is creating some fastening problems. New finishes are being applied to metal fasteners to help reduce corrosion, and adhesives are being used for such areas as lightweight trim moldings. To reduce product liability risks, automakers are using more fasteners with self-locking thread forms, or chemical thread coatings and other locking devices. Wholesale product revamping and the consolidation of more body stampings are resulting in fewer welds. In some structural and hang-on part applications, welding is replacing mechanical fastening to reduce weight, complexity and assembly time. Lighter-weight component design is increasing electron beam and friction welding prospects, and corrosion-resistant material use in body components is modifying welding techniques. Meanwhile, U.S. fastener manufacturers face the problem of the growing influx of imported ferrous fasteners, mainly from Japan. A list of fastener supplies is provided in a separate section.

DEBATE BETWEEN SECRETARY ADAMS AND GM PRESIDENT ESTES. MAC NEIL/LEHRER REPORT, MAY 28, 1979

A transcript is provided for a televised interview of Brock Adams, Dept. of Transportation (DOT) Secretary, and Elliot Estes, General Motors (GM) President, by Robert MacNeil and Jim Lehrer of the Educational Broadcasting Co. Under discussion is DOT's challenge to the auto industry to reinvent the automobile in order to meet future energy demands. Mr. Adams emphasizes the need for basic research and evolutionary approaches to develop a new car by 1990 to meet fuel economy needs which he believes will surpass the mandated 27.5 mpg for 1985. Mr. Adams feels that 50 mpg fuel economy is a realistic expectation for the year 2000. Mr. Estes does not dispute the need to improve cars and fuel economy but questions the meaning of "reinventing the car". He sees 50 mpg as a realistic goal but sees possible problems in the price range and consumer acceptability of a new design to meet this figure. Mr. Estes emphasizes GM's redesign of 90% of its cars in three years and the resulting 5 mpg improvement in fuel economy. Mr. Adams and Mr. Estes are in agreement on the need for basic research on thermodynamics, combustion, fluid dynamics, and structures.

THE AUTOMOBILE REPAIR RIPOFF. THE MAC NEIL/LEHRER REPORT, MAY 24, 1979

The transcript is provided for a televised interview of Joan Claybrook, Administrator of the National Hwy. Traffic Safety Administration (NHTSA); Donald Randall, an attorney for the Automotive Service Council; Robert McMen, Deputy Director of the New Jersey Dept. of Motor Vehicles; and Tom Hanna, senior vice president and chief operating officer of the Motor Vehicle Manufacturers Assoc., by Robert MacNeil and Jim Lehrer of the Educational Broadcasting Co., on the subject of fraud in the auto repair industry. The interview stemmed from a recent release of results of a Dept. of Transportation (DOT) undercover survey of repair shops in seven cities showing that $.53 of each dollar spent was wasted. A three-day meeting sponsored by DOT brought together industry, consumer, and government representatives to investigate the repair industry problem. Those interviewed were leading participants in the meeting. Ms. Claybrook agrees that the consumer often has a 50/50 chance of being cheated for repair work, and that it is difficult to bring a criminal charge against a dishonest mechanic. The NHTSA Administrator supports diagnostic centers separate from repair shops, but considers them probably economically infeasible on a national level. She supports better repair provisions built into cars. Mr. Randall states that fraud constitutes the smallest part of the problem, which involves training and confidence of service technicians and increasing complexity of the car. Mr. McMen presently feels that the State of New Jersey should not be involved in automotive diagnosis, but is in favor of mechanic training and possible state licensing. Mr. Hanna acknowledges that the auto industry is offering extended warranties to allay consumer anxiety about repairs; he cites efforts by the industry to promote mechanic training and certification, and opposes diagnostic centers, and standardized diagnostic provisions in cars. Ms. Claybrook, additionally, advises consumers to read car repair information material, to learn to do minor repairs, and to familiarize themselves with state laws.

A STRATEGY FOR OPTIMIZATION OF DIESEL FUEL INJECTION SYSTEM

A strategy is outlined for finding and realizing the best compromise between fuel injection parameters and diesel engine engineering targets. The application of the strategy is demonstrated using actual results of a study based on optimization of exhaust emissions and fuel economy for a diesel passenger car. The strategy for the optimum adaptation of a fuel injection system to a diesel engine includes reduction of the fuel injection system parameters to be optimized in the test, selection of the optimization points, and determination of the optimum adaptation at which all target requirements are met. The optimum design of a fuel injection system can be practically determined by the systematic variation of two injection parameters: start and duration of injection. This applies without qualification to indirect injection and by meeting certain nozzle design and injection pressure boundary conditions for direct injection. Since the optimization points are not expressly specified by the engine manufacturer or by legislation, their selection is best based on the frequency distribution of load and speed in the particular test procedure. It is possible to determine representative operating points which also take transient operation into account. The optimum design is presented and analyzed in the form of an overlap area from isograms in which the target requirements are boundary lines for the start and duration of injection.

LATENT STRUCTURE MODELS APPLIED TO THE JOINT DISTRIBUTION OF DRIVERS' INJURIES IN ROAD ACCIDENTS

The same distribution of injury severities (fatal, serious, slight, and uninjured) sustained by the two drivers involved in head-on collisions between two vehicles of equal mass is considered using latent structure models for analysis of contingency table data. Rural accident data for Great Britain for the period 1969-1972 are examined. The positive correlation between the injury severities of the two drivers is explained by the speed of the automobiles involved in the accident, a variable which is not recorded in national accident statistics and is thus "latent".

EVALUATION OF MOTOR VEHICLE EMISSIONS INSPECTION AND MAINTENANCE PROGRAMS IN OHIO. PHASE 3. FINAL REPORT

Recent data for the State of Ohio indicate that the National Ambient Air Quality Standards for carbon monoxide and photochemical oxidants will not be attained in all areas of the state by 1982, even if all reasonably available control technologies are applied. In view of this, it is likely that the state will request from the Environmental Protection Agency an extension of the compliance date beyond 1982. In order for this request to be considered, the state, among other things, must have adopted a firm schedule for implementing a motor vehicle inspection and maintenance (I/M) program in the highly urbanized nonattainment areas. The State of Ohio is currently planning for the implementation of such a program. Detailed analyses performed as part of this effort are presented which cover the costs, benefits, personnel requirements, direct and indirect impacts, and scheduling requirements associated with the particular program option being considered.

A MANAGEMENT SYSTEM FOR EVALUATING TRAILER/MOTORCYCLE, AUTO/TRUCK, AND REJECTION RECEIPTS IN THE VIRGINIA PERIODIC MOTOR VEHICLE INSPECTION PROGRAM. FINAL REPORT

An enhanced version of the original system for management evaluation of trailer/motorcycle, rejection, and auto/truck approval receipts issued under the Virginia periodic motor vehicle inspection (PMVI) program is described. The procedures are described which were developed for calculating the appropriate sample sizes and for providing a method of sampling which may be used to determine a statewide failure rate for each item inspected and for vehicles of different type, age, and mileage categories. A procedure is also outlined and software provided to implement an evaluation of stations suspected of improper inspection practices. This method compares failure rates for individual stations to the statewide norms. A coding and keying manual for processing information from inspection receipts is appended. This new management system provides for evaluation of the Virginia PMVI program at a lower cost and with greater accuracy than was previously possible. Among the recommendations are implementation of a method for positively identifying the mechanic performing an inspection, an improved method for determining true vehicle mileage, use of a different configuration for trailer/motorcycle rejection receipts, and modification of the present filing system.

DYNAMICS OF WHEELED RECREATIONAL VEHICLES

This compilation of eight papers presents recent research results on the kinematics, dynamics, stability and control of wheeled recreational vehicles (RV's), including camper trailers, vans, boat trailers, bicycles, motorcycles, dune buggies, and snowmobiles. Emphasis is on the modeling of the underlying physical phenomena governing the dynamic behavior of wheeled RV's. The effect of wheel-roadway interaction phenomena in the development of realistic dynamic models of trailers and two-wheeled vehicles is discussed in considerable detail, with a separate example of its effect on the behavior of a steady-turning vehicle-trailer system. The effect of lateral hitchpoint stiffness is studied, and some very useful analytical and experimental methods for determing trailer stability are presented. The effect of numerous parameters affecting trailer stability is examined in detail; the effects of roll steer and drawbar flexibility are addressed, as well as control and safe operation of RV trailers. The off-road stability of RV's is studied; novel approaches from ship stability theory and catastrophe theory are introduced which prove to be useful and effective for stability analysis with very rough terrain.

CHARACTERIZATION OF WHEEL-ROADWAY INTERACTION FOR RECREATIONAL VEHICLES

Seven mathematical models for the interaction of a pneumatic tire with a roadway are analyzed using a single-wheel trailer and assuming that the tire and roadway touch each other at only one point. The following cases are modeled: rolling without slip alternating with sliding, rolling without slip alternating with side slipping, side slip with side force proportional to slip angle, slipping with horizontal contact force proportional to slip angle, and tire with one, two, or three degrees of freedom (accounting for tire elasticity by introducing a rigid tire that is elastically connected to a hub). Results of numerical solutions are given in graphical form for the first four models. Significant disparities are found among the predictions of the various theories. This work is intended to form the basis for experiments to determine which model, if any, is, in fact, valid.

EFFECT OF HITCHPOINT LATERAL STIFFNESS ON TRAILER STABILITY

The effect on trailer stability of hitchpoint lateral stiffness and damping is examined using a model which is a one degree of freedom, nonholonomic, dynamical system and yields a third order linear differential equation. Trailer stability criteria are developed, and stability charts are presented which depict the stability criteria in terms of nondimensional parameters. The analyses show that increasing hitchpoint lateral stiffness does not improve trailer stability, whereas increasing hitchpoint lateral damping is much more important to trailer stability. It is further shown that the percentage of trailer weight carried by the hitchpoint (i.e. hitchpoint loading) is very important to trailer stability; generally, the greater the value of hitch loading the smaller the trailer's unstable region. Other important factors in trailer stability are the trailer's mass, mass distribution, and geometric construction. Generally, when the difference is reduced between a positive, nondimensional parameter characterizing these three trailer aspects and a parameter representing the fraction of trailer carried by the hitch and characterizing the trailer loading condition, the trailer's stability is improved and hitchpoint lateral damping requirement reduced.

THE INFLUENCE OF DRAWBAR FLEXIBILITY AND ROLL STEER ON THE STABILITY OF ARTICULATED VEHICLES

In order to determine the effects of roll steer and drawbar flexibility on the stability of articulated recreational vehicles, and whether these effects are independent, comparisons are made of the stability predictions from four different articulated vehicle models (one with rigid drawbar and no roll freedom, one with flexible drawbar and no roll freedom, one with rigid drawbar and roll freedom, and one with flexible drawbar and roll freedom). The models are compared in terms of a critical forward speed above which constant speed motion in a straight line is unstable. It is found that roll freedom (through roll steer) does affect stability. Negative front and positive rear roll steer are stabilizing; positive front roll steer and negative rear roll steer are destabilizing. Over a large range of values, drawbar stiffness and damping do not affect stability if roll steer is not present. Drawbar flexibility can significantly affect stability when roll steer is present. A decrease in drawbar stiffness can be either stabilizing or destabilizing. For sufficiently low values of drawbar stiffness, critical speed can be dramatically lower than the critical speed associated with a rigid drawbar. The mode of instability associated with low values of drawbar stiffness is different from that with higher values. Changes in drawbar damping significantly affect stability for sufficiently low values of drawbar stiffness, but not for higher values.

RELATIVE SIGNIFICANCE OF PARAMETERS AFFECTING LATERAL STABILITY OF ARTICULATED RECREATIONAL VEHICLES

A seven-degrees-of-freedom model of an articulated recreational vehicle is described and used to determine the relative significance of parameters and of degrees of freedom that affect lateral stability. Thirty-five parameters are used to describe tire-road interactions, roll freedom, suspension systems, geometry, mass distribution, the hitch, the drawbar, and the forward speed. Critical speeds associated with different systems are calculated; for a particular set of articulated vehicle parameters (e.g. weights, moments of inertia, dimensions), a critical forward speed exists above which constant speed motion in a straight line is unstable. It is concluded that roll freedom and roll steer must be included in the model, with the former not dependent on the presence of the latter. In such a model, decreasing the size of the powered vehicle or increasing the size of the towed vehicle is destabilizing. Negative front and positive roll steer of the powered vehicle are stabilizing. The change in critical speed due to an increase in front roll steer corresponds to that due to a comparable decrease in rear roll steer. Negative roll steer of the towed vehicle is destabilizing, and a certain amount of positive roll steer is stabilizing but large amounts dramatically lower critical speed. Cornering stiffness values are critical, more so for the powered vehicle. Cornering stiffness and roll steer coefficient changes are the most significant. Hitchpoint location changes do not significantly affect lateral stability. The addition of hitch damping has almost no effect on lateral stability. Over a wide range of values, changes in drawbar stiffness and damping are not significant. However, for sufficiently low values of drawbar stiffness, these two parameters become extremely important; in such cases, the critical speed is also very sensitive to roll parameter changes of the towed vehicle.

A SIMPLIFIED ANALYSIS OF THE STEADY-STATE TURNING OF ARTICULATED VEHICLES

The steady-state turning behavior of vehicles pulling trailers is formulated in a simplified manner using the concept of a handling diagram. The handling diagram graphically relates steer angle, path radius, and speed. The formulation assumes small slip angles but admits a nonlinear relationship between the slip angle and side force of the tires. The handling diagram concept can be used on more elaborate linear models by replacing the real slip angles and stiffness of tire pairs with their effective slip angles and stiffness. This work parallels that of Pacejka (1973) which was done for a single vehicle. It is noted that the method for determining jack-knife stability disregards flutter properties of the trailer.

DETERMINATION OF TRAILER STABILITY THROUGH SIMPLE ANALYTICAL METHODS AND TEST PROCEDURES

Approximate factors, measurement techniques, and test procedures are provided which can be used to determine the stability of trailers being towed by cars. The recommended performance measure is damping ratio, or an equivalent cycle to half amplitude, which is evaluated via a pulse-steer procedure at some reference speed. A minimum damping ratio criterion of 0.15 at 55 mph is suggested and compared to the results of recent full-scale tests. The approach is useful in selecting a minimum value of hitch load (for various weights of tow cars) that will ensure a minimum acceptable level of trailer stability at highway speeds. Improved trailer damping can be obtained by designs that stress low inertia, long wheelbases, heavy-duty tires, and large tow-car-to-trailer weight ratios.

STEADY TURNING OF TWO-WHEELED VEHICLES

After a brief review of studies on the dynamics of two-wheeled vehicles, steady turning of two-wheeled vehicles is analyzed in terms of a theory which accommodates large lean angles and a realistic representation of wheel-roadway interaction. Quantitative and qualitative relationships between rider and bicycle behavior are explored in detail and the effects of vehicle parameter changes on motorcycle behavior are examined. A description of the vehicle, the definitions of symbols used, and the equations underlying the analysis are presented. The method of solving the equations is discussed, and results of numerical solutions are presented in graphical form and discussed. This study furnishes the basis for the design of experiments that could be used to gain valuable insights into the interdependent forces on a turning two-wheeled vehicle and rider.

OFF-ROAD STABILITY OF RECREATIONAL VEHICLES

An attempt is made to lay the analytical foundations for a theory of the stability of off-road recreational vehicles, using the theory of ship stability rather than the traditional theory of on-road vehicle stability. The type of terrain most applicable to this approach is a sloping terrain with many rocks and potholes inducing significant angular perturbations of the vehicle. The linear theory is discussed, as well as driving on a rough slope, pitching, vertical oscillations, and large angles. The methods of catastrophe theory as originally presented by Zeeman are used in an attempt to explain the behavior of the off-road vehicles.

EXPERIMENTAL AUTOMOBILE-PEDESTRIAN INJURIES

Fifteen fresh cadaver impacts were conducted in simulation of pedestrian-automobile accidents. The test sled configuration simulated an automobile bumper and hood in "standard" and "nose-dive" situations as well as "hard" and "soft" impact surfaces. Instrumentation and film demonstrated large axial compression forces in the struck leg and considerable angular velocity of the torso in all modes. Dissection revealed primary injury at the impact site at low velocities with added remote injury at high velocities. Fracture of the lateral tibial plateau was most common. Lowering the bumper height offered the greatest protection against injury at moderate impact velocities.

OFF-ROAD VEHICLE ACCIDENTS: A NEW SPECTRUM OF TRAUMA

A survey of off-road vehicle accident injuries indicated a significant incidence of trauma; means of 931 serious injuries and 15 fatalities annually were reported for a three-county region of Southern California. A representative 78-bed community hospital in the desert region saw 542 patients with injuries related to off-road vehicle (dune buggies, motorcycles, four-wheel-drive vehicles) accidents over three years. Three-fourths of all patients had head injuries or injuries to the extremities; 47% of upper extremity and 31% of lower extremity injuries involved fractures. There were 37 isolated clavicle fractures. The majority of spine injuries were compression fractures in the thoracolumbar region. Characteristic injuries could often be related to the type of accident and vehicle involved. A survey of off-road vehicle enthusiasts showed that 21% had had an accident resulting in injury. Driver immaturity, poor judgment, and alcohol were identified as causative factors. Future planning must include attention to the sports enthusiast and medical services planning as well as an appreciation of the characteristic injuries resulting from this sport.

ALTERNATIVE SURVEILLANCE CONCEPTS AND METHODS FOR FREEWAY INCIDENT MANAGEMENT. VOL. 1: EXECUTIVE SUMMARY. FINAL REPORT

The main components of low-cost freeway incident management are described, including the questions of quantifying the problem and of cost-effective selection of low-cost freeway incident management options for implementation. Emphasis is placed on the development of pre-planned response techniques, candidate jurisdictional agreements, traffic operational procedures for incident sites, and overall improvement of freeway incident management. This volume of the 6-volume report is designed to give police, highway, and traffic engineering administrators a conceptual understanding of the issues surrounding freeway incident management in less than an hour of reading time.

EVALUATION OF MOTOR VEHICLE EMISSIONS INSPECTION AND MAINTENANCE PROGRAMS IN OHIO. PHASE 2. FINAL REPORT

Seven candidate motor vehicle inspection and maintenance (I/M) program configurations were analyzed from the standpoint of costs, benefits, and other requirements, from which the State of Ohio will select one specific option. Recent data indicate that Ohio cannot attain National Ambient Air Quality Standards for carbon monoxide and nitrogen oxides by 1982, even if all reasonably available control technologies are applied. A firm schedule for implementing an I/M program is prerequisite to obtaining an extension of the compliance date. All seven candidate (I/M) programs have the following elements in common: idle mode testing, annual inspection, motor vehicle registration enforcement, and Ohio Environmental Protection Agency and Bureau of Motor Vehicles as administrative agencies. Major issues identified in setting up an I/M program include type of emission test (idle or loaded), geographical coverage, organizational approach (government, contractor, or private garage), frequency of inspection, and enforcement procedure. More specific design issues include types of motor vehicles to be tested, vehicle exemptions, data handling, mechanic training, quality assurance, consumer protection, and public education.

BATTERY POWERED ELECTRIC VEHICLES. STATE-OF-THE-ART 1978

An introductory section discusses the need for electric vehicles (EV's) brought on by the energy crisis and pollution problems, the Lead Industries Assoc.'s EV program, the lead-acid type battery as the only viable power source for EV's at present and for the near term, electric energy for battery charging, and recycling as the key source of lead for batteries used to power EV's. A truck section discusses the use of electric pickup and delivery trucks in commercial fleets, the potential market for EV's in the major use categories of the U.S. commercial truck market, electric truck producers (Battronic Truck Corp., Electric Vehicle Associates, EVA-Chloride Electrovan Corp., Jet Industries, Inc., AM General), the Postal Service electric truck program, and the National Capital Region (division of the National Park Service) EV fleet (special service trucks, passenger car). A section on passenger cars presents a car[illegible]ule review of current electric passenger car manufacturers (S[illegible]ing-Vanguard, Elcar Corp., Electric Vehicle Associates, Inc., General Electric/Dept. of Energy, General Motors Corp.), describes various projects using electric passenger cars, and highlights typical new experimental cars (Globe-Union, Sears Roebuck and Co.). A section on buses describes activities of U.S. companies (Battronic Corp., Electric Vehicle Associates-Chloride Electrobus Corp.) presently producing battery-powered buses, and outlines the current use of electric buses in various operations throughout the U.S. A final section discusses the development of electrics in foreign countries (Japan, England, Italy, France, Holland, Germany, and Canada). Each page of the text contains photographs of EV's. Addresses of U.S. EV and battery manufacturers are listed.

VEHICLE ACCIDENTS AT MAINTENANCE AND UTILITY WORK ZONES

A study was undertaken to determine the magnitude and characteristics of safety problems, in terms of reported accidents, that are associated with moving vehicular traffic around and through highway maintenance and utility work zones. This was done by examining 280 maintenance and utility work zone accidents that occurred on the Virginia state highway network over a period of 14 months, representing approximately 0.4% of the total number of accidents reported during that period. A review of accident reporting procedures indicated the omission from the sample of a variety of work zone accidents where the roadway was not under physical repair (e.g., sweeping and landscaping) or where the first event in the accident was not related to the work activity (e.g., driver falling asleep). Several characteristics of the maintenance and utility work zone accidents are discussed, including general and specific locations of the accident, time of day, roadway and environmental factors, characteristics of the work zone, cause of the accident, and accident severity. Where data were available, comparisons were made between the maintenance and utility work zone accidents and all reported accidents. Recommendations for future research include studies to determine how much additional care should be taken by drivers in highway maintenance and utility work areas, and the most effective ways of communicating the need for increased caution. Highway work area traffic control procedures should be evaluated by criteria other than reported accidents, since the "Road Under Repair" designation may be interpreted differently by different reporting police officers.

CAR-FOLLOWING HEADWAYS ON FREEWAYS INTERPRETED BY THE SEMI-POISSON HEADWAY DISTRIBUTION MODEL

Driver car following patterns on freeways were investigated, particularly as a function of traffic flow level, using a headway distribution model. A number of "two-component" vehicular headway distribution models assume that vehicles on a road can be divided into two groups according to whether or not they are interacting with the vehicle ahead. A model of this type, the "semi-Poisson" model proposed by Buckley, is applied to a data base consisting of 42,000 observed headways from a single lane of an urban freeway over a range of flow from 900 to 2000 vehicles per lane per hour. A previously developed computational method allows the distribution of followers headways to be calculated directly from the observed total headway distribution by numerically solving an integral equation without introducing a parametric form for the followers distribution. The resulting followers headway distribution is found to be independent of the flow with a mean of 1.32 sec. and a standard deviation of 0.52 sec. No statistically significant discrepancies are found between the model results and the observed data. The theoretical basis for the semi-Poisson model is discussed and compared with those of other models in order to assess the plausibility of the interpretation with respect to car following. Evidence suggests that the capacity of freeways is generally limited not by the size of following headways acceptable to drivers but by the difficulty of producing a steady flow of traffic in which nearly all vehicles are followers. The flow independence of the followers headway distribution indicates that car following in freely flowing freeway traffic in the flow regime studied is essentially a nearest-neigbor interaction in which the individual driver is influenced mainly by the vehicle ahead rather than by more global aspects of the traffic environment such as the overall flow level.

STABLE PHASE-PLANE AND CAR-FOLLOWING BEHAVIOR AS APPLIED TO A MACROSCOPIC PHENOMENON

An attempt is made to furnish plausible explanations for some observed traffic-flow phenomena, based on known behavior of a pair of cars in a car-following situation. A fundamental psychophysical approach is applied deterministically in assessing actual driver performance. Observation of driver behavior in the traffic stream indicates that there are trajectories which loop clockwise in the phase (spacing/relative speed) plane. Based on these observations, and on a car-following equation appropriate for a two-regime (free-flow and congested-flow) phenomenon, an approximate limit cycle in the phase plane (switch-type behavior) is derived. The enveloping curves to these limit cycles may represent actual relatively close spacing conditions. It is realized that the intersection point of an approximate enveloping curve and a threshold curve for detecting relative speed at a given spacing has an important property, and may be associated with the critical spacing which represents transition between the congested-flow and free-flow regimes.

A RECREATION VEHICLE FOR YOUR FAMILY. PT. 2 OF A TWO-PART SERIES ON RECREATIONAL VEHICLES (RV'S)

Motorized recreational vehicles (RV's) are discussed for the consumer. The five types of motorized RV's are described: motor homes on heavy-duty chassis, van campers in which bodies are converted to living accommodation, van campers equipped with partial life support systems, "chopped vans" or "mini" motor homes, and truck campers. The development of motorized RV's and their recent production history are outlined. The prices of RV types and incomes of RV owners are given. Arguments commonly heard for and against using a motorized RV (vs. a trailed unit) are enumerated. Some general advice is given concerning the selection of an RV, and servicing and maintenance of RV equipment are discussed. Addresses are provided for campground directories and services, magazines and publications, and for the Recreation Vehicle Industry Assoc. as a source of general information.

HOW SAFE ARE FEDERAL-AID HIGHWAYS?

Safety reviews of Federal-aid highways were conducted in the 50 states during the winter and spring of 1978 by Federal Hwy. Administration (FHWA) and state highway agency resource personnel. The reviews had two objectives: to determine if recently completed highway projects were following current safety concepts of providing a forgiving roadside environment, high design standards related to roadway geometrics and surfaces, and adequate guidance and control for the road user; and to determine if older Federal-aid highways were being upgraded to current safety standards in a timely and effective manner. It was determined that current safety criteria and concepts are being incorporated into new Federal-aid construction, producing a safer highway environment. Progress made in the past ten years was seen in the use of breakaway sign and light supports and crash cushions, and clear recovery areas along the roadside. Some exceptions to the general highway safety quality of new highway projects included the continued use of curbs on high-speed roadways. The timely safety upgrading of older sections of Federal-aid highways was found to be still a major national problem. Only a few states have aggressively improved the safety features of their older Interstate system, and very little general upgrading of safety features is being accomplished on the non-Interstate Federal-aid system. It was found that because of either a misunderstanding of the performance of highway safety features (e.g. breakaway sign supports, cable guardrails) or because of rigid conformance to a specific design detail, the safety performance of the end product was sometimes compromised. It was also found that very few highway agencies were using accident data to evaluate the safety performance of highway features. The most serious problem encountered by the review teams concerned the wide variation in safety policy between different states and FHWA regions in such areas as pedestrian accommodations and narrow bridge warnings.

FUEL UTILIZATION OF ARTICULATED VEHICLES: EFFECT OF GROSS VEHICLE WEIGHT

Computer simulation techniques were used to study the effects of gross vehicle weight (GVW) and other design and operating factors on fuel consumption of tractor trailer trucks. Vehicles were classified into eight GVW/axle configuration categories from 18 tons GVW to 44 tons GVW and three body types (platform, van, and tanker trailers). For each class, a representative vehicle was selected and its fuel utilization was calculated over a representative duty cycle. The effects were evaluated of plausible modifications to vehicle and engine design and operating parameters. The results show that some GVW configurations above the present legal limit (U.K.) of 32.5 tons can yield improvements in fuel efficiency provided that existing load factors are maintained. If a fleet were composed of vehicles on 5 axles at 38 tons GVW or 40 tons GVW, these fuel savings might be gained without causing additional road damage, if the fourth power law relating road damage to axle weight is applied. The use of vehicles on 4 axles at 36 tons GVW and on 5 axles at 44 tons GVW would increase road damage. Single-drive configurations are 4% to 5% more fuel efficient than double-drive configurations. Application of a package of possible economy measures has been shown to give 18% fuel economy improvement; the package includes the construction of lighter tractive units and trailers, reduction in aerodynamic drag, use of low governed speed engine matched to a suitable transmission, and use of a demand-actuated cooling fan.

PROTECTION OF OCCUPANTS OF COMMERCIAL VEHICLES BY INTEGRATED SEAT/BELT SYSTEMS

Five different types of integrated seat belt systems (i.e. belt anchorage incorporated in the seat) were evaluated in frontal crash experiments at an impact speed of 35 kph, using dummies in a truck cab on a catapault unit. Results were compared with those obtained with conventional three-point belts and with unrestrained dummies. The experimental results show that when the dummy was unrestrained or protected only by a lap belt (even if integrated), the upper load limits used as protection criteria were far exceeded because of the heavy impact on the steering wheel; this did not apply to the three-point belt systems. Very favorable forward displacement kinematics were achieved using special seats of adequate structural strength with integrated three-point belt systems; the load on the occupants' bodies was within acceptable limits, and the occupants did not hit hard against the cab interior. The experiment showed that a vibration-absorbing seat with integrated three-point belt and additional supports fitted to the seat and backrest is the optimum solution.

INJURY MECHANISMS TO FULLY RESTRAINED OCCUPANTS

Selected data are presented from a year-long accident investigation study in the Montreal (Canada) area of 74 cases where one or more fully-restrained (lap and shoulder) vehicle occupants received injuries of OAIS (Overall Abbreviated Injury Scale) 2 or greater. Only 11 of the accidents involved occupant injuries greater than OAIS 3. Over 85% of the 84 occupants (53 drivers, 31 right front passengers) had OAIS 2 or 3 injuries. For OAIS 2 and 4, a higher percentage of passengers, and for OAIS 3, 5, and 6, a higher percentage of drivers were involved. Fifty-five percent of drivers vs. 35.5% of passengers were injured in frontal impacts. Head injuries were sustained by 30% each of drivers and passengers. Over 15% of drivers vs. 4% of passengers had facial injuries. Eleven percent of drivers and 15% of passengers received chest injuries. The steering wheel was responsible for 25% of drivers' injuries. Restraint system webbing was responsible for 2.1% of drivers' and 11.4% of passengers' injuries. The near side was involved in 35%, and the roof in 45% of the cases in which intrusion increased injury severity. In no case did the restraint system retain the occupant so as to increase injury severity. Recommendations include a driver restraint system with a retractor which removes slack rather than simply tightens, replacement of Chrysler window blind retractor with a locking retractor, and greater occupant compartment integrity (especially vehicle roof and sides). Appended are a discussion of problems encountered during the study, and descriptions of the more severe OAIS injury cases.

SEAT DESIGN--A SIGNIFICANT FACTOR FOR SAFETY BELT EFFECTIVENESS

Production seats and specially designed research seats were analyzed with respect to seat/safety belt interaction under frontal crash conditions in order to evaluate seat influences on three-point belt effectiveness. As Federal Motor Vehicle Safety Standard 208 loading criteria alone were determined to be insufficient for evaluation of the seat's influence on safety belt effectiveness, supplementary evaluation parameters of dummy kinematics were defined to analyze more or less biomechanically favorable points and directions of application of restraint forces on the vehicle occupant. It is concluded that optimization of the restraint system cannot be achieved until seat optimization is accomplished. Present safety regulations concerning head-on collisions concentrate essentially on the safety belt and not on seat and seat frame deformation characteristics. It is proposed that the design of a safe seat should begin with the design of the forward seating area to provide a seating reaction force of proper direction and magnitude, i.e. so that a balance of the moments at the pelvis and lumbar spine exists in interaction with the remaining external forces (lap belt forces and the force of inertia).

RESPONSE OF BELT RESTRAINED SUBJECTS IN SIMULATED LATERAL IMPACT

Far-side lateral impacts were simulated using a Part 572 dummy and human cadavers (embalmed and unembalmed) to compare responses for several belt restraint configurations. Sled tests were conducted with a velocity change of 35 kph at a 10 g deceleration level. From field data, it was estimated that this velocity change of the laterally struck vehicle represents about an 80th percentile level for injury-producing lateral collisions. Subjects restrained by a three-point belt system with an outboard-anchored, diagonal shoulder belt (i.e. positioned over the shoulder opposite the side of impact) rotated out of the shoulder belt and onto the seat. The subject received some lateral restraint due to interaction with the shoulder belt and seatback. The subjects restrained by a three-point belt system with an inboard-anchored, diagonal shoulder belt (i.e. positioned over the shoulder on the side of impact) remained essentially upright due to shoulder belt interaction with the neck and/or head. Kinematic responses of the Part 572 dummy were generally similar to those of the cadaver subjects. Injuries were found in cadavers restrained by both shoulder belt configurations, but were more extensive to the cervical region for those subjects receiving direct neck and/or head loading from the belt. Limitations in the cadaver model and test environment, as well as the preliminary nature of the experiments, do not permit definitive conclusions on the significance or applicability of the injury data obtained to real accident situations. Appended is a discussion of the effect of age on intervertebral disc structure.

PERFORMANCE OF A SHOULDER BELT AND KNEE RESTRAINT IN BARRIER CRASH SIMULATIONS

Previous pendulum impact tests have shown that knee joint injuries and tibial-fibular fractures may occur when loads are directed against the lower leg rather than directly against the femur in the knee. In order to further improve understanding of lower extremity restraint mechanics, simulated frontal barrier crash experiments were conducted with unembalmed human cadavers and an anthropomorphic dummy restrained by two-point shoulder belts. In the first test, an experimental bolster was specifically positioned so that the cadaver's lower leg would strike the bolster, thus inducing restraining loads entirely below the knee joint. The analysis of occupant kinematics showed that the flexed knee rode over and forward of the low-positioned bolster. Restraint induced considerable shearing load across the knee joint. Bolster measurements indicated a peak load of approximately 4.0 kN per leg which resulted in a contralateral, central tear of the posterior cruciate ligaments. Factors influencing shoulder belt and knee restraint system performance were studied in the remaining experiments. Positioning the bolster to provide full knee contact and early femoral loading, and orienting the bolster face to reduce knee joint shear loads (approximately 38.5 degrees from horizontal) were identified as important parameters for improved performance of the knee restraint. The reaction force vector of the deforming bolster structure (approximately 32.5 degrees from horizontal) represented an additional independent factor in minimizing contact loads and in controlling occupant kinematics. Under these knee constraint conditions, an average peak bolster reaction force of 6.2 kN per leg (compared with a dummy femur load of 5.9 kN) did not result in injury to the lower extremity of four cadavers. It is indicated that a two-point shoulder belt and knee restraint system can control occupant kinematics and attenuate potential lower extremity injury during a 13.4 m/sec frontal crash simulation.

SIMULATION OF SIDE IMPACT USING THE CAL3D OCCUPANT SIMULATION MODEL

By applying some advanced features of the CAL3D occupant simulation model, a single model incorporating the vehicle structure and a simplified occupant were developed for studying the sensitivity of occupant response to parameter changes in perpendicular, vehicle-to-vehicle side impacts, not involving vehicle rotation. Results of the model show qualitative agreement with published experimental results. Occupant responses are sensitive to the initial clearance between the occupant and the door inner surface, the stiffnesses of the front structure of the impacting vehicle, and the side structure of the impacted vehicle. Although door intrusion is an important factor affecting occupant response, it is hypothesized that the occupant response is more sensitive to the kinematics of the door than to peak intrusion. Door intrusion seems to affect the efficiency of the padding between door and occupant, i.e. thicker padding will be required to limit peak occupant responses to preselected levels for vehicles with lower side structure stiffness.

INJURIES TO PEDESTRIANS IN REAL ACCIDENTS AND THEIR RELATION TO COLLISION AND CAR CHARACTERISTICS

Data are presented from an analysis of 3000 pedestrian/motor vehicle accidents which occurred in Germany during 1975 and 1976. The primary contact area in over half of the accidents was the outer third of the vehicle front end; the center of the front end was implicated in about 15% of the accidents. For 75% of injury-producing accidents, impact speeds were in the range up to 30 kph. Head and leg injuries, especially lower limb injuries, predominated. Abdominal injuries were frequent, with chest and vertebral injuries relatively infrequent. In frontal collisions, almost one-fourth of elderly adult pedestrians involved suffered a severe/fatal head injury. The elderly were overrepresented in fractures of the lower limb, pelvis, and upper thigh. Child pedestrians (20% of pedestrian casualties) had a very high incidence of head, chest, abdominal, and upper thigh injuries. Overall pedestrian injury severity was about the same for "v" and "pontoon" vehicle shapes, with some advantage for the v shape. Lower limb injuries were overrepresented for v forms, while a higher incidence of abdominal and upper thigh injuries were found for pontoon forms. Critical areas of pedestrian contact for v forms were windshield frame, windshield, and bumper/front end area. For the pontoon form, critical areas were the rear part of the hood/lower windshield frame area and the front edge of the hood. In one-fifth of the accidents, the windshield was destroyed. In critical/fatal injury accidents, 52.4% of windshields of v-form cars were destroyed, vs. 33% for pontoon-form cars.

COMPARISON OF PASSENGER INJURIES IN FRONTAL CAR COLLISIONS WITH DUMMY LOADINGS IN EQUIVALENT SIMULATIONS

A method is presented which correlates injuries in real accidents with experimental dummy loadings, and is applied to injury data for 318 occupants wearing safety belts who were involved in frontal car-to-car collisions. The relationship of real and simulated accidents is based on an Equivalent Accident Characteristic (EAC) for defining accident severity. From analysis of accident and simulation data, a reference factor, delta v (velocity change), was established. By elimination of the accident characteristic delta v (the EAC) a direct relationship between real injury and dummy loading was established. Corresponding dummy loadings for subcritical Abbreviated Injury Scale values are given. The tolerance limit for fatal head injuries was found at about Head Injury Criterion 1600, a higher than previously assumed value. The tolerance limit of the chest of Severity Index 1000 was confirmed. For pelvic/abdominal injuries, the tolerance limit was determined to be 74 g.

INFLUENCE OF MASS RATIO AND STRUCTURAL COMPATIBILITY ON THE SEVERITY OF INJURIES SUSTAINED BY THE NEAR SIDE OCCUPANTS IN CAR-TO-CAR SIDE COLLISIONS

An analysis of 1344 car-to-car side collisions which occurred in France indicated that the risk of serious or fatal injury to occupants of struck vehicles increases proportionally to the difference in vehicle mass ratios in favor of the striking vehicle. In-depth analysis of 90 collisions in which the side panel of the passenger compartment was impacted, revealed that the difference in mass ratios was not the principal determinant of injury severity. Injury frequency and severity correlated better with the amount of side panel intrusion occurring when the bumper and structure in front of the side rail of the striking car override the rocker panel of the struck car. Lightest cars are exposed to maximum intrusion, since the stiffest elements of the side of the body shell are rarely involved. When the struck car/striking car mass ratio is less than or equal to 0.85, the initial contact of the striking vehicle is located above the rocker panel in 65% of the cases. Overriding the rocker panel doubly penalizes the occupant seated perpendicularly to the intruding panel because it increases the depth of penetration (and, all things being equal, the occupant/panel contact velocity) and raises the point of intrusion so that the occupant's chest strikes a stiffened panel at the impact interface. Chest injury predominates for these near-side occupants, with pelvic and abdominal injuries occurring a little less frequently and head injuries much more rarely. An appreciable increase in protection could be afforded by stiffening the low parts of the body shell, just above the rocker panel.

FEMORAL LOADS MEASURED BY A SIX-AXIS LOAD CELL

A six-axis femoral load cell was designed, fabricated, calibrated, and tested in an ATD (anthropomorphic test device) upper leg. The cell has linear characteristics with adequate output and dynamic response. Its output compared well with that of load cells mounted behind a knee bolster which was impacted by an ATD instrumented with this load cell. Although the axial load was found to be well below the present limit of Federal Motor Vehicle Safety Standard 208, the bending moments were found to be high. A conservative tolerance limit for axial load should be considered, and cadaver data are required.

EPIDEMIOLOGY OF CHILDHOOD MOTOR VEHICLE RELATED ACCIDENTS

Statistics are reviewed of the involvement of children in motor vehicle-related accidents in the U.S. and in various countries worldwide. In 1977 in the U.S. alone, there were 4700 motor vehicle-related deaths and over 180,000 disabling injuries of children from birth to age 14 years. A Washington State seat belt study is reported, covering accidents in which children were involved from 1 Jan 1970 to 31 Dec 1977. Results of this study show the beneficial effect of seat belts in reducing injuries and fatalities among children. The emergency room and hospitalization experiences at Mary Bridge Children's Health Center in Washington State during 1978 are cited to illustrate the medical impact on children of motor vehicle-related accidents. This brief survey demonstrates that motor vehicle-related injuries are common, that patterns of injury can be identified, and that remedial steps must be taken to reduce future accident rates.

CAR SEAT SAFETY--PAST, PRESENT, AND FUTURE

A brief historical review of the development of child car seat in the U.S. is followed by a discussion of one car manufacturer'

(Strolee of California) approach to the development of a philosophy concerning the "total performance" of a child seat. The development of child seats is traced from the early "hook-over" type, to the "hook-under" type, and then to the car seats built to meet Federal Motor Vehicle Safety Standard (FMVSS) 213, a standard based on static load tests. The course of action taken by Strolee in developing the next generation car seat is described. The company wanted to maintain the desirable features of its products (child's ability to see out, child comfort, reclinability, age span, price consideration, ease of installation, appearance, ease of child entry and removal) while meeting FMVSS 213 requirement as well as to make them compatible with dynamic testing requirements. To provide a suitable level of child safety, the company decided that the following items would have to be satisfied: contain the child within reasonable limits during 30 mph, 20 g type tests (20 mph side and rear impact tests also investigated), provide for child and parent comfort, make the seat useful for the entire age span a child would require, and make it attractive, easy to install, and easy for both child and parent to use. Examples are given of the difficulties and uncertainties facing the child car seat manufacturer in meeting the proposed FMVSS 213-80 which covers dynamic testing.

NHTSA (NATIONAL HIGHWAY TRAFFIC SAFETY ADMINISTRATION) CHILD SAFETY ACTIVITIES

The nature and magnitude are outlined of the problem of child fatalities in motor vehicle accidents (as passengers, pedestrians, or bicyclists). Special mention is made of children riding in the luggage space of station wagons and hatchback cars. In 1978, about 4,200 children died in motor vehicle accidents. Exclusive of early childhood diseases, approximately 16 percent of the child fatalities, ages 0-14, are the result of such accidents. The unrestrained child in a passenger car becomes a missile during a crash, projected to any part of the occupant area, and ejection from the vehicle is a major cause of death. Restraints for various age groups of children, such as belts and child seats, are discussed, and dynamic tests with anthropomorphic dummies are described, as well as plans for additional restraint studies and biomedical research. Proposals have been made to revise the child restraint system (FMVSS 213) to extend the scope to include infant carriers and harnesses in addition to child seats, and to require dynamic testing. Promising results have been obtained with vehicle soft front ends which are more forgiving to pedestrians. Public information programs to increase restraint usage by children are presented along with a discussion of behavioral countermeasures dealing with the pedestrian and bicyclist/motor vehicle accidents. Further research is recommended to obtain basic performance data on retrofit or after-market type padding and to prescribe standard testing methods (including those for flammability and toxicity) in order to upgrade the safety performance of older school buses. Operational and hardware problems are discussed concerning the safe transport of handicapped school bus and transit bus riders.

SOME FACTORS INFLUENCING THE INJURIES SUSTAINED BY CHILD PEDESTRIANS STRUCK BY THE FRONTS OF CARS

The relative importance of child pedestrian accidents is considered by reference to national accident statistics for Great Britain. Data from a study using existing hospital and police records are used to examine the location of initial pedestrian contacts with the vehicle and the effects of initial contact on overall injury severity. In particular, the incidence of "run over" accidents is examined, and it is shown that, contrary to popular belief, the very young child is rarely run over when struck by the front of a car or car derivative. The injuries sustained by child pedestrians struck by the fronts of cars or light trucks/vans are described, and differences in injury patterns according to age examined. About three-fourths of all child pedestrians are struck by the front of a car (or derivative). The younger the child, the more likely the first contact is with the side of the vehicle. In general, children, once involved, are less likely to be killed than adults. The very young child is more likely to be killed than the older child, due to the young child sustaining a direct blow to the head or torso from the relatively stiff front edge of the hood vs. the older child's head striking the top surface of the hood. The effects of vehicle front end height on injuries is considered, and it is shown that when the front end height is 60%-70% of pedestrian height there is an increased risk of neck injury. Reducing the stiffness of the front structure and of localized stiff areas on the top surface of the hood is recommended to reduce the incidence of severe injuries in pedestrian/motor vehicle accidents.

CHILD RESTRAINT EVALUATION BY EXPERIMENTAL AND MATHEMATICAL SIMULATION

Two child restraint system sled tests with a child cadaver and a three-year-old child dummy demonstrated some differences between the kinematical response of dummy and cadaver. Two mathematical models were formulated to evaluate child restraint performance, using the MADYMO program package, a general purpose, mathematical, dynamical model for crash victim simulation developed at the Res. Inst. for Road Vehicles (TNO), Holland, in collaboration with the Netherlands Inst. for Road Safety Res. (SWOV). A description is presented of the validated dummy and cadaver models, together with experimental and model results. A sensitivity study was conducted to provide better insight into the effects of various parameters on the child's response. To demonstrate the use of the model as a design tool, the results of a simulation using an energy-absorbing backstrap vs. the standard belt are presented. It is concluded that the mathematical model is a better simulation for the cadaver kinematics than the dummy.

DEVELOPMENT OF TESTING AND EVALUATION OF CHILD RESTRAINT SYSTEMS AND CHILD TEST DUMMIES BY NHTSA (NATIONAL HIGHWAY TRAFFIC SAFETY ADMINISTRATION)

The three-year-old child dummy Model VIP-3C, produced by Alderson Res. Labs. was selected, on the basis of its construction, kinematic responses, and measurement characteristics, to be further tested by the National Hwy. Traffic Safety Administration (NHTSA) as a device for evaluation of child restraint systems in automobile crashes. Static and dynamic tests were developed to calibrate this dummy, slightly modified and designated as the SA103C. Calibration involved the measurement of head and chest accelerations and the bending characteristics of the neck and lumbar section. Tests were conducted with four dummies at two labs (NHTSA's Vehicle Res. and Test Center, and the Univ. of Michigan's Hwy. Safety Res. Inst.) to account for any differences in measured responses. Four calibrated dummies were further evaluated in simulated frontal crashes in two representative child restraint-automobile crash environments to determine the repeatability of their responses obtained in replicated testing. Six repeated tests were made with each dummy in 30 mph impacts with the "GM Love Seat" (belt type) and with the Chrysler "Mopar" (shield type). Three repeated tests were made with each dummy at 20 mph with the GM seat's top tether straps disconnected. All four dummies gave repeatable measurements of head and chest accelerations and head and knee excursions, and were sufficiently sensitive to detect crash environment differences. Results of testing 23 different child restraint systems in 30 mph and 20 mph simulated crashes with infant and three-year-old-child dummies indicate structural failure of a number of these systems and the potential for dynamic testing to uncover these and other performance problems.

TESTS AND MATERIALS FOR SCHOOL BUS RETROFIT APPLICATIONS

Methods and materials were investigated that might be used to retrofit protective materials for older model school bus seats, modesty panels, and stanchions. Laboratory tests were conducted under Federal Motor Vehicle Safety Standard (FMVSS) 222 guidelines on these components, under conditions with and without commercial retrofit materials, using head and knee forms. Additional tests were conducted on five potential retrofit materials. From results of 390 tests, it is concluded that the dynamic portions of FMVSS 222 could be applied to older model school buses for retrofit applications. The seat back and modesty panel rails were found to be the most dangerous objects for potential facial injuries, while head contusion injuries appeared not to be a problem. It was determined that commercial materials are available that can be used to minimize facial injuries. Commercial retrofit padding satisfied FMVSS 222 knee and head form criteria on the seat backs but not seat back or modesty panel rails. Thicker commercial padding advertised as Ensolite, Rubatex, or Ethafoam did improve the force-energy values significantly and would be acceptable under FMVSS 222 criteria.

HEAD IMPACT RESPONSE COMPARISONS OF HUMAN SURROGATES

The response of the head to impact in the posterior-to-anterior direction was investigated with live anesthetized and postmortem primates, in order to relate animal test results to previous head impact tests using cadavers, and to study the differences between the living and postmortem state in terms of mechanical response. The three-dimensional motion of the head, during and after impact, was derived from experimental measurements and expressed as kinematic quantities in various reference frames. In addition to standard anatomical and predefined laboratory reference frames for describing head motion kinematics, Frenet-Serret frame fields were used. The experimental technique used a nine-accelerometer system, mounted rigidly to the head, to measure head motions. Additional measurements included impact force, epidural pressure, and strains in the skull bone. High-speed cineradiography (1000 frames/sec) was used during the impact. The effects of the following factors are discussed: relative magnitudes of brain mass, skull mass, and external soft tissue mass; head surface geometry at the impact site, and mass distribution; and differences in epidural pressures and in head trajectories.

THE RESPONSE OF UNEMBALMED CADAVERIC AND LIVING CEREBRAL VESSELS TO GRADED INJURY--A PILOT STUDY

An investigation was undertaken of the propensity for rupture of living and unembalmed cadaveric canine cerebral vessels when subjected to similar injury. A 10 g mass was dropped from varying heights onto the exposed brain in both the living and cadaveric states. The postmortem cerebral vessels were reperfused with an ink marker at living pressures to simulate normal vascular distention with blood. Both living and cadaveric vessels ruptured in response to the same energy (100 cm gm. to 400 cm gm.) and failed to rupture below these levels (50 cm gm.). It is suggested that the physical integrity of postmortem cerebral vessels is adequate for the vessels to serve as indicators of brain injury in response to various loads. This vascular injury should be more pertinent to the investigation of traumatic brain injury than the propensity of load to fracture the skull, since the occurrence of skull fracture in trauma is inconsistently related to brain injury.

DIFFERENTIAL TOLERANCE OF FRONTAL AND TEMPORAL LOBES TO CONTUSION INDUCED BY ANGULAR ACCELERATION

An analysis was made of frontal and temporal lobe contusions of rhesus monkey brains that were caused by a single sagittal plane angular acceleration impulse. At neuropathological exam, the depth, extent, and location of contusions were mapped and described according to a classification previously developed for human subjects. Of 30 monkeys subjected to the single impulse, 13 had no frontal or temporal contusions (Group 1), 8 had only frontal contusions (Group 2), and 9 had temporal contusions (Group 3). Correlation with angular acceleration, tangential acceleration, and tangential force showed that the three groups were statistically different. The mean peak positive tangential force for Groups 1-3 was 541, 659, and 766 newtons, respectively. This suggests that as mechanical impact increases, frontal contusions occur before temporal ones, and that the threshold is less for frontal than for temporal contusions. If this relationship is true, one would predict that, if there is sufficient input to cause a temporal contusion, a frontal contusion should also be present. In fact, in Group 3, 8 of the 9 animals with temporal contusions also had frontal contusions. Furthermore, the frontal contusions in Group 3 were statistically more extensive than either the frontal contusions of Group 2 or the temporal contusions of Group 3. These data support the concept that, in angular acceleration, the threshold for frontal contusions is less than that for temporal contusions. Since it is felt that the data best support the hypothesis that these contusions result from deceleration contact forces, the threshold differences relate to regional differences of mechanical input vs. differences in tissue mechanical properties.

ACCELERATION INDUCED SHEAR STRAINS IN A MONKEY BRAIN HEMISECTION

A freshly dead Stumptail (Macaca speciosa) monkey brain hemisection model was subjected to translation, pure rotation, and a combination motion. Linear and angular head accelerations were measured, as well as brain displacement relative to the skull and shear strain at several locations. Much (4 times) higher than previously predicted shear strain was measured at acceleration levels which have been recorded during impacts which produced concussion in live monkeys. Pure rotation produced the highest, most diffuse, and longest lasting shear strain and brain displacements, while translation produced very low shear strain. Highest shear strain during rotation was recorded in the brainstem rather than on the periphery as many have predicted. Results suggest that the mechanism of brainstem injury, regardless of head motion, is due to shear caused by stretching of the cervical cord. The model is inadequate to show that stretching can occur in translation if relative motion between neck and head occurs.

INTRACRANIAL PRESSURE RELATIONSHIPS IN THE PROTECTED AND UNPROTECTED HEAD

Research was continued on closed head impact in the human cadaver and an associated mathematical model, the long-term goal being to describe relationships between head impact events which might be useful in understanding what occurs in the living human. In the current study, two different sets of experiments were conducted: sequential impacts on a single embalmed specimen with helmet, and impact experiments on individual unembalmed specimens with helmets. Measured impact parameters and intracranial pressures are discussed. A finite-element model is presented which can predict the intracranial pressures throughout the brain for the first 8 msec. It is apparent that the helmet prevents high-magnitude, short-duration intracranial pressures. The highest positive pressures develop in the frontal lobe and propagate in the posterior direction. Low-magnitude, negative pressures develop in the posterior fossa during head acceleration and propagate in the anterior direction. Positive posterior pressures develop after the acceleration phase.

FURTHER VALIDATION OF THE SIMULATION MODEL OF AUTOMOBILE COLLISIONS PROGRAM

To improve the utility of the SMAC (Simulation Model of Automobile Collisions) program and to assess its limitations, 12 vehicle-to-vehicle collisions were staged and then reconstructed with the program. A variety of impact configurations included 60 degree front-to-side, 90 degree front-to-side, 10 degree offset head-on, and 10 degree offset rear-end. Agreement between the measured data and the SMAC reconstructions was found acceptable. The final rest position, velocity change, and damage profile of the vehicles were used to assess the accuracy of the simulations. The vehicle rest position was, by far, the most sensitive parameter to variation in input changes. Velocity change was the least sensitive; fine tuning the input to obtain an acceptable match with rest position, in general, had little effect on predicted velocity change. Of the collision configurations, the 60 degree front-to-side was the most difficult to reconstruct. This was attributed to the lack of any corner stiffness effects in the simulation of the vehicle structure, such that the onset of the collision interface in the struck vehicle was not steep enough. In a number of collisions, one or more of the wheels on a particular vehicle became airborne. Since the program does not include weight transfer effects, simulation of these effects was limited to setting the cornering stiffness to zero on the appropriate wheels, obviously only a partial solution.

A COMPARISON BETWEEN PART 572 DUMMY AND HUMAN SUBJECT IN THE PROBLEM OF SUBMARINING

In an effort to determine why Part 572 dummies have a greater tendency to submarine than human cadavers in car crash tests, differences in their pelvic shapes and abdominal flexibilities were studied. Anthropomorphic data were obtained on human volunteer subjects, the Part 572 dummy, and 28 human skeletons; X-rays were taken of the volunteers and the dummy; a comparative study was made of the pelvic triangles of the skeletons, the dummy, and FAA-USAF NHTSA model; static tests of abdominal flexibility were conducted on the dummy and volunteers with variations in the tension of the seat belt, which was placed on the abdomen over the sartorius. Results demonstrated that the differences in the direction of the sartorius, or upper notch (situated between the anterior-superior and anterior-inferior iliac spine), in the pelvic position relative to the vertebral column in the sitting position, and differences in the abdominal flexibility are the main reasons for the submarining difference between the Part 572 dummy and the human subject. Consequently, the shape of this notch, the foam rubber in the abdominal portion, and the whole abdominal insert of the Part 572 dummy were modified. A transducer was designed to measure directly the compression load when the lap belt intrudes into the abdomen during dummy submarining. This affords a practical method for establishing the abdominal injury criteria of submarining. Some car crash tests on the modified dummy and the current dummy equipped with transducers produced satisfactory results.

BIODYNAMICS OF THE LIVING HUMAN SPINE DURING -GX IMPACT ACCELERATION

Spinal kinematics of living human volunteers (students aged 18-25) undergoing -Gx impact acceleration are described, along with experimental procedures followed in data acquisition. Four males and three females were subjected to impacts in the tensed and relaxed mode from two g to eight g, in one g increments. Their lower extremities were clamped tightly to the impact seat, and the pelvis was restrained by a lap belt. The biodynamic response of the living spine was found to be quite similar to that of the cadaveric spine, particularly in terms of T1 displacement, acceleration at T1, and flexural resistance. Females have a weaker neck musculature and tended to withdraw from the test program at lower g levels than males because of transient neck pain.

POSTURAL INFLUENCES ON THORACIC IMPACT

The influence of body posture, and inherent support, on thoracic impact response was investigated in an animal model. Six anesthetized and six postmortem, domestic, male swine were exposed to blunt, midsternal loading while supported in their natural quadrupedal posture, and the results were compared with previously reported data from similar tests involving an upright body orientation. Each animal was impacted once by a 21 kg, rigid mass with a flat contact interface moving at a nominal velocity of either 8 m/sec or 10 m/sec. Measured mechanical responses included applied load, sternal and spinal accelerations, thoracic compression, and aortic overpressure. Injury response was assessed from a thoracico-abdominal necropsy. Electroencephalograph (ECG) traces were recorded pre- and post-impact to monitor electrophysiological response. Anesthetized animals suspended in their natural posture sustained serious pulmonary hemorrhage without skeletal damage, whereas the upright-suspended subjects suffered multiple rib fractures and instances of liver laceration. ECG changes occurred in both postures, although these were generally minor for the quadrupedal orientation. Ventricular fibrillation did not occur in any natural posture test despite peak sternal accelerations up to 1300 g's, but occurred in all upright posture tests with peak sternal accelerations exceeding 700 g's.

A STUDY OF DRIVER INTERACTIONS WITH AN INFLATING AIR CUSHION

Mechanical driver surrogate interactions with an inflating air cushion mounted on the steering wheel (General Motors' air cushion restraint system (ACRS)) were studied using test environments with various initial occupant-air cushion separations or air cushion module modifications. Static tests using a rigidly-mounted body block placed in the path of the inflating cushion showed how interaction forces might be developed when the body block interacted with the inflating cushion. The magnitude of the peak interaction force was an inverse function of the initial separation between body block and cushion. When the body block was initially in close proximity of the cushion, the interaction force was characterized primarily as a pressure existing between the steering assembly and the body block, peaking during the early phases of cushion unfolding. The lack of whole body motions and the rigidity of the body block have an effect on interaction forces, and the test responses do not address the responses of a human in such exposure. Static and dynamic inflation tests performed with the Hybrid III thorax placed in line with the path of the ACRS provided a more realistic simulation. The Hybrid III dummy allowed whole body motions, body articulation, and chest compression, although there are many differences between the dummy and car occupants. Peak chest compression was considered the best of the measured responses to compare the dummy-ACRS interaction for the various test conditions.

A 30 MPH FRONT/REAR CRASH WITH HUMAN TEST PERSONS

A test program was undertaken in order to prove that a human subject in a standard automobile, wearing a standard lap and diagonal seat belt, can withstand a certain, precisely-defined level of accident severity without sustaining any injuries, and to establish whether there are differences in the loading imposed on a human subject and a test dummy at this level of accident severity. Following a series of sled tests using human volunteers and Hybrid II dummies, front/rear crashes at 30 mph using standard Audi 80 cars were conducted with the human and dummy subjects in the driver's position, wearing a lap/shoulder belt. Results demonstrate that a human driver in a standard automobile and protected by a standard seat belt system can withstand an accident of a certain severity without being injured. It was established that both the belt forces and the head acceleration values are considerably lower with human occupants than with test dummies. This is largely related to the fact that the human driver can brace himself with his arms on the steering wheel. The results could conceivably be extrapolated for higher accident severity levels.

MODIFICATION OF PART 572 DUMMY FOR LATERAL IMPACT ACCORDING TO BIOMECHANICAL DATA

The Part 572 dummy was modified in order to improve its performance in lateral impact studies. The rib cage, arms, and shoulders of the dummy were modified so its impact performance more closely simulates that of a human. Based on biomechanical data obtained on cadavers during lateral collision tests, the Part 572 arm was modified by reducing the size of the structural members and increasing the padding, and the mobility of the shoulder was increased in both forward and upward directions. The shoulder was modified to become transversely collapsible to a certain degree. The rib cage was redesigned to give a more realistic deformation. The measurement of lateral chest deflection was also incorporated into the rib cage design, while frontal impact characteristics were left unchanged. Results of freefall and full-scale crash tests, both frontal and lateral impacts, are compared for the modified dummy and cadavers. Preliminary results are encouraging; further developments are expected.

EVALUATION OF HUMAN TOLERANCE IN FRONTAL IMPACTS

Results are analyzed of ten accident reconstructions of five actual frontal car collisions which involved nine restrained occupants. The reconstructions were first carried out using dummies, and then using cadavers. Injuries sustained in the real accidents are compared with the injury criteria values recorded for dummies, and with injuries and injury criteria values found for cadavers. From the results, it appears that an Abbreviated Injury Scale 3 head injury in a real accident can be associated with a lower value than the 500 Head Injury Criterion value recorded for the Part 572 dummy. There was a large scatter in chest injury criteria values; for protection of almost all occupants, a limit value should be chosen that is lower than the proposed value of 60 g's. The cadavers showed more extensive thoracic fractures than the actual passengers under the same crash configuration, taking into consideration the Eppinger theory concerning the number of fractures related to age, weight, and shoulder belt force value. The results confirm that the fresh cadaver, under certain conditions, is a satisfactory model for biomechanical studies.

CHARACTERISTICS OF DWI'S (DRIVING WHILE INTOXICATED), ALCOHOLICS, AND CONTROLS

The literature is reviewed pertaining to characteristics of individuals arrested and convicted for driving while intoxicated (DWI). Summaries and/or typical examples of the data found in the reviewed papers are given for various social and personal demographic characteristics. Appended are abstracts of selected references, and tabulated statistics comparing characteristics of control drivers (i.e. all drivers randomly selected to represent the total driving population), DWI's, and alcoholics. The data clearly suggest that the current population of DWI's contains a high proportion of alcohol abusers who are likely to be repeat DWI offenders. A composite profile of the DWI driver indicates that he is most often a male, aged 30 to 45 years. He is more likely to be separated, divorced, or widowed than the control driver. He has less education, less income, and greater unemployment or job difficulties due to his drinking. He reports drinking more often and with larger quantities of alcohol than the control driver. There are indications of psychosocial disturbances with drinking behavior reflective of stress and difficulties. The DWI driver has a worse driving history and drinks and drives more often than the control driver. On variables which indicate problem drinking behavior and life disturbances, DWI drivers resemble alcoholics. The DWI requires a serious, comprehensive program to counter his trends toward alcoholism. Positive outcomes require speedy and thorough intervention. Based on experience with treating alcoholics, it is considered that rapid progress in overcoming DWI problems is unlikely. Countering the drinking driving problem requires some means of reversing the behavior of drinking drivers who are not apprehended as DWI and who appear to differ in characteristics from the DWI.

DRINKING-DRIVER PROBATION SHOULD BE EVALUATED FROM A PROBATION PERSPECTIVE

It is emphasized that all DWI (driving while intoxicated) probation functions of the National Hwy. Traffic Safety Administration's Alcohol Safety Action Projects (ASAP's), including screening, reporting, classification, referral, and coordinative functions, should be the sole responsibility of the existing probation office responsible for that particular jurisdiction. On occasion, enabling ASAP-type legislation has been introduced, usually by a state highway department, and often even passed by state legislatures with no coordination through probation systems at any state or local level. Because of this fragmented planning, problems have been imposed upon local probation offices which lacked sufficient staff to effectively handle the additional caseload, or sufficient community resources for referral of DWI offenders. By not interfacing with existing probation agencies at the local, state, or even Federal level, the ASAP-type DWI probation office was often set up on an unsound basis of probation organization or management. Various attempts at evaluating drinking-driver probation programs, for the most part, have failed to recognize the need to evaluate the probation phase, its operations and administration. With a built-in mechanism for the evaluation of the quality of casework and supervisory services within a DWI probation office, there is no way to ensure that the offender is being provided the best services.

TRAFFIC SAFETY IMPACT OF MANDATED LICENSING ACTIONS RELATIVE TO ALCOHOL ABUSE TREATMENT PROGRAMS OR FINES AND/OR JAIL SANCTIONS

An evaluation was made of the efficacy of three treatment approaches (mandated licensing controls, no licensing action, or participation in a 12-month alcohol abuse treatment program) as traffic safety measures for California drivers convicted of multiple DUI (driving while under the influence) offenses. Standard fines and/or jail sentences were used in all three approaches. Statistical analyses of subsequent driving records demonstrated that the use of mandated licensing action (suspenion or revocation) in addition to fines and/or jail sentences had a more positive effect on traffic safety than the use of only fines and/or jail sentences or the use of fines and/or jail sentences in combination with a 12-month alcohol abuse treatment program. Both the magnitude and duration of the effect of the individual treatment approaches in terms of subsequent DUI or accident involvement are documented.

IMPLEMENTATION OF A LARGE SCALE REHABILITATION PROGRAM EVALUATION (DRUNK DRIVING OFFENDERS)

The background is reviewed of the National Hwy. Traffi Safety Administration-sponsored Short Term Rehabilitatio

(STR) Study for DWI (driving while intoxicated) offenders. Problems encountered in implementing the study and some actual and potential solutions to these problems are discussed. The 1975 STR Study involved the conduct and evaluation of rehabilitation activities at 11 Alcohol Safety Action Project sites. Treatment modalities included alcohol safety schools, non-PMT (Power Motivation Training) group therapies, and individual therapy as well as PMT. Explicit experimental designs which employed procedures for random assignment of DWI clients to treatment or control groups were developed at each of the sites. The study was designed to provide an empirical demonstration of the effectiveness of short-duration, court-supervised rehabilitation programs for DWI offenders. A critical requirement was the development of procedures to randomly assign clients to treatment and no-treatment categories. The 11 sites also assumed significant responsibilities for the collection of various data for evaluation purposes. Discussed are the experiences with gaining acceptance of the use of random assignment to treatment and the use of no-treatment control groups, the implementation of random assignment, determining evaluation criteria, and data collection problems.

THE APPLICATION OF "STATE OF THE ART" INTERVENTION AND EVALUATION TECHNOLOGY: PROSPECTS FOR THE FUTURE OF THE ALCOHOL AND TRAFFIC SAFETY COUNTERMEASURES APPROACH

The philosophical and empirical developments are examined which have occurred within the ASAP (Alcohol Safety Action Project) education and rehabilitation programs over the past decade. A number of regrettable, yet not unpredictable failures, both of the ASAP intervention approaches and of the methods that have been used to evaluate them are addressed. It is suggested that the ASAP may have been both a success and a failure. The most pressing problem currently confronting the ASAP system is to understand its positive and negative results. Unfortunately, the evaluation technologies which have been applied to the system to date have been incapable of sensitive analysis. It is suggested that recent trends in theory and practice of both alcohol abuse treatment and program process and outcome evaluation have much to offer the ASAP countermeasure approach; these emerging concepts are detailed. Rules for performing treatment outcome evaluations in the alcohol field (pretreatment measures, treatment outcome measures, and follow-up procedures) are outlined.

JUDICIAL INTERVENTION: THE MISSING ELEMENT (ALCOHOLISM PREVENTION AND REHABILITATION)

The opportunity for judges, through the constructive use of the power of their office, to direct persons convicted of alcohol-related (A/R) offenses to the most suitable treatment, is discussed. With the exception of a few outstanding court-oriented alcoholism prevention and rehabilitation programs, most courts are still using the traditional, nonproductive jail and fine approach. A careful investigation of the relatively few successful programs indicates that success is directly related to an individual judge's education and motivation toward an enlightened approach in helping an individual overcome alcohol abuse or alcoholism through education and counseling, while utilzing community resources. In most cases, the lack of successful programs in the majority of courts can be directly attributed to the lack of motivation and, to a lesser extent, to the lack of appropriate education of individual judges. Judges, in common with the general public, have been subjected to a very strong cultural bias against the alcoholic and a very strong media bias against the DWI offender. Judges typically view these persons as deserving of some type of punishment, and apply the traditional jail and fine approach rather than innovative ways of treatment. These attitudes can be changed if a process of judicial education is implemented. An outline is presented of a model for a weekend educational seminar for judges concerning alcohol and A/R driving offenses.

THE ADDICTED DRIVER: A PROBLEM OF LAW OR MEDICINE?

It is expressed that society (and the justice system in particular) has not yet made a decision on how to deal with the crime of driving under the influence (DUI) of alcohol or other drugs, what penalties are proper and effective, how to provide an enforcement capability, and whether or not this is a major crime deserving of priority attention from the judicial system. Most conspicuously lacking in the justice system is any uniform direction; there are no practical and specific guidelines. The justice system is the most ideally equipped facet of society for providing motivation to the addicted driver to obtain treatment for his illness. The DUI crime constitutes a problem of top priority in the American justice system. Some concerned judges, especially in states where decriminalization followed the Uniform Intoxification and Alcoholism Treatment Act, are utilizing such diversionary practies as pre-trial probation, suspended sentences with probation, pre-sentence investigations, and civil commitments to treatment.

THERE IS MORE TO A DWI (DRIVING WHILE INTOXICATED) CASE THAN A BAC (BLOOD ALCOHOL CONCENTRATION) READING: A JUDGE'S RESPONSIBILITY TO THE DRINKING DRIVER

The need is discussed for judges to understand the significance of a BAC (blood alcohol concentration) reading in DWI (driving while intoxicated) cases, to attempt to identify the potentially dangerous drinking driver, and to try to tailor the sentence to help the defendant overcome his dependency on alcohol. Judges, in giving great weight to BAC readings, tend to overlook revealing facts that could give them insights into a DWI offender's alcohol involvement. Judges can identify the existance of a drinking problem even though a defendant denies he has one, but many times they tend to empathize with a DWI defendant. Most judges and law enforcement personnel have no concept of the quantity of alcohol that must be consumed to reach a BAC of .10% (present legal presumption of intoxication) and higher. The BAC reading is a most useful indication of a person's drinking habits. Other suggested factors a judge should consider include the age of the defendant, time of day of arrest, where and why drinking took place, emotional state, the decision to drive when drunk, facts surrounding probable cause for a DWI arrest, and observations at the scene. A judge's role is to make some determination that a drinking problem exists, that a defendant before him may be potentially dangerous, and then to direct him into some treatment. A judge can tailor a sentence to the specific needs of a defendant, and must recognize his responsibility to highway safety goals inherent in all DWI laws.

THE DELPHI PROJECT ON THE VIEW OF CRIMINAL JUSTICE OFFICIALS ON ALCOHOL SAFETY ADJUDICATION AND REFERRAL COUNTERMEASURE EFFECTIVENESS

A discussion is presented of the Delphi Project (1976-1977) for establishing the varied perceptions by judges and other criminal justice officials of the most or the least effective driving under the influence (DUI) adjudication and referral (A and R) countermeasure actions. The Delphi Project tested two DUI A and R effectiveness hypotheses through Alcohol Safety Action Project (ASAP) judges and other ASAP criminal justice officials (CJO's) and non-ASAP judges. Contrary to Hypothesis I, non-ASAP judges rated DUI case referral processing measures higher in effectiveness than the adjudication and referral procedures, machinery and personnel measures. In accordance with Hypothesis I, non-ASAP judges rated alternative case processing and sanctioning techniques, and effectiveness measures and uniform policies measures lower in effectiveness than adjudication and referral procedures, etc. Contrary to Hypothesis I, ASAP judges and other ASAP CJO's held the same countermeasure views as non-ASAP judges. Contrary to Hypothesis II, both non-ASAP and ASAP judges and other ASAP CJO's rated DUI referral measures, such as providing for adequate referral and treatment capabilities, higher in effectiveness than adjudication measures, such as streamlined case disposition. Project background, the Delphi method (judgments obtained from each member of panel(s) of experts, with anonymous controlled feedback of group responses to each member, and development of a group consensus), project design and implementation, data analysis, and findings are described. Attached are a listing of action items that primarily improve driving under the influence of intoxicating liquor adjudication or case referral, a ranking of ten highest and lowest ASAP countermeasures by each of two panels (mean effectiveness and standard deviation calculations), and a detailed ranking of each countermeasure by category and subcategory.

AN HONEST IMPLIED CONSENT LAW (DRIVING WHILE INTOXICATED OFFENSES)

It is argued that implied consent and per se laws will have to be amended so as to state explicitly a true law-science relationship. These amendments must include a concise statement that the usual presumptions are to be considered as interpretive of the test result at the time the test is given, and not as a standard of guilt of any offense. All breath analysis test results must be admissible in evidence subject to challenge for accuracy or for any inference to be made therefrom. Test results should be regarded as corroborative evidence of other facts that establish the corpus delicti of the DWI (driving while intoxicated) offense or as rebuttal evidence pertaining to affirmative defenses. The method for administering breath tests must follow the scientific analytical procedure of two blanks, two breath samples, and at least one standard test. Only tests performed within 120 minutes measured from the DWI occurrence should be considered as possibly probative of the DWI offenses, stated as 120 minutes from an on-view arrest situation and 90 minutes from arrest for any other offense. The refusal case should be heard as a summary proceeding following the DWI case, with judicial discretion to impose a penalty of suspension of driving privileges up to one year's duration. Such amendments will return enforcement procedures to a reliance upon detailed data collected by the police at the scene of the arrest, only to be corroborated by chemical test data. The detailed arrest information and data from the breath test are essential to convincing the offender of the guilt of the DWI offense, a precursor to entry into any time-saving-diversionary program and valuable in making a diagnosis of alcoholism. An amended Illinois implied consent law is appended.

SEMINARS ON ALCOHOL AND HIGHWAY SAFETY FOR STATE AND LOCAL LEGISLATORS

The content of a 13-hour (one evening, one day) seminar developed for state and local legislators on the subject of alcohol and highway safety, and application of the materials (pilot testing in Maryland and Iowa) are decribed. The primary purposes of the seminar were as follows: to inform legislators of the national, state, and local pictures of alcohol abuse and its effects on driving behavior and highway accidents; to make the lawmakers aware of the research data that support the alcohol countermeasures legislation recommended by the National Hwy. Traffic Safety Administration (NHTSA); to assure that legislators understand the potential impact of new laws on their state's alcohol-related traffic accidents; and to provide the basis for a plan of legislative action to draft and pass laws which structure the Alcohol Safety Action Project's drinking driver control system. Positive reactions from participants in the pilot tests indicate that the seminar project was successful in attaining the primary objective of raising the legislators' consciousness of the alcohol/highway safety problem. Seminar staff and NHTSA personnel concluded that the seminar, as originally conceived, was the most effective way to communicate the alcohol/highway safety information to state legislators. It was also concluded that the preparations and scheduling are most critical to seminar success. Specific recommendations for successful conduct of such seminars for lawmakers at all levels are outlined and cover scheduling, seminar host, location, group size, and resource personnel.

THE VISUAL DETECTION OF DRIVING WHILE INTOXICATED

As the initial phase of a two-phase project on the visual detection of DWI (driving while intoxicated), an on-the-road study was conducted which resulted in the identification of visual cues and the development of detection procedures for effectively discriminating between DWI and DWS (driving while sober). (The second phase will field test the developed detection guide.) Statistical analyses of 1681 cue occurrences recorded during 643 detection events determined a set of 23 visual cues accounting for 92% of the cue occurrences. The cues are as follows: stopping (without cause) in traffic lane, following too closely, turning with wide radius, appearing to be drunk, driving on other than designated roadway, straddling center or lane marker, almost striking object or vehicle, slow response to traffic signals, headlights off (at night), signaling inconsistent with driving actions, weaving, tires on center or lane marker, drifting, swerving, accelerating or decelerating rapidly, slow speed (more than 10 mph below limit), fast speed (more than 10 mph above limit), failing to respond to traffic signals or signs, braking erratically, stopping inappropriately other than in lane, turning abruptly or illegally, driving into opposing or crossing traffic, and driving with vehicle defect(s). A cue is typically observed with one or more other cues, but few subsets of specific cues occur together frequently. There are large differences among cues in their DWI frequency, and in their ability to discriminate between DWI and DWS. Generally, conditions under which cues occur have little influence on their frequency. Patrol strategy (general vs. that with DWI emphasis) greatly affects relative observance frequencies.

R.I.D.E. (REDUCE IMPAIRED DRIVING IN ETOBICOKE): A PREVENTION PROGRAMME FOR DRINKING DRIVING

A drinking-driving program, R.I.D.E. (Reduce Impaired Driving in Etobicoke), introduced in one borough of Toronto, Canada, is evaluataed. Based on evidence from previous campaigns judged effective, the program combined a highly visible "random" spot-check enforcement component with extensive media coverage and a drinking-driving educational component. A three-wave telephone survey showed significant increases in public knowledge of the drinking/driving problem and of the R.I.D.E. program. The subjective perception of arrest risk was increased for the "average driver" but not for "myself". Although only indirect evidence was available on driver behavior, this tended to indicate fewer impaired drivers on the road. Police-reported alcohol-related (A/R) accidents and injuries indicated an overall downward trend in Toronto, but the urban nature and restricted size of the experiment's geographic unit, as well as similar changes in control areas and data inconsistencies and bias, did not permit conclusive results to be drawn in terms of reduced A/R accidents and injuries, and lowering of blood alcohol concentrations.

EFFECTS OF ALCOHOL AND DIAZEPAM, SINGLY AND IN COMBINATION, ON SOME DRIVING PERFORMANCES

Fourteen drivers were given practice and then used in four separate sessions under alcohol alone (0.08%), diazepam, (a minor tranquilizer) alone (up to 10 mg), both alcohol and diazepam, or no drugs, and tested in three driving tasks. The driving tasks were carried out on an airport taxiway in a full-size passenger car. The tests consisted of steering through a serpentine course at 25 mph to 40 mph; carrying out an evasive maneuver involving either a sudden lane change to the left or right, or a sudden braking maneuver involving stopping the vehicles as close as possible to a point on the road, from speeds of 25 mph to 40 mph; and a speed reproduction and maintenance task in which drivers had to attain a speed between 25 mph and 40 mph and maintain it as steadily as possible, without the use of the speedometer. The steering tests were clearly found to be affected by variations in task difficulty, manipulated by driving speed; and test-retest reliability was adequate. There was considerable intersubject variability in driving performance, as well as in the effects of alcohol and diazepam. Significant decrements in performing evasive maneuvers resulted after ingestion of alcohol and/or diazepam, and a similar, but not statistically significant trend was found for steering in the serpentine course. No significant drug effect was found in terms of speed reproduction, speed maintenance, or controlled braking performance. There was no significant interaction of alcohol with diazepam.

DEVELOPMENT AND EVALUATION OF A TRAFFIC SAFETY AND ALCOHOL PROGRAM FOR SENIOR ADULTS

The development and evaluation is described of an educational program entitled "Senior Adults, Traffic Safety and Alcohol," designed to alert senior adults to their special vulnerability to traffic fatalities and the role of alcohol in these tragedies as well as in some of the other personal and social areas of their lives. The program was developed and evaluated in the following six steps: a survey of the population for whom the program was intended, establishment of goals, writing and field testing of a criterion instrument, design and production of program, field testing of program, and analysis of program. The one-hour program consists of an 11-minute animated film and an accompanying six-page pamphlet, and a discussion period. Evaluation results show that the experimental subjects, when compared with control subjects, achieved a higher score on the knowledge measure, exhibited more positive attitudes, and indicated more positive behavioral intentions. (The total package comprises the animated film, take-home pamphlet, a leader's guide, and a manual that discusses all aspects of the program. It is available through the AAA Foundation for Traffic Safety, 8111 Gatehouse Rd., Falls Church, Va. 22042.)

PRINCE GEORGE'S COUNTY: A LOCAL HEALTH DEPARTMENT CONFRONTS THE YOUNG DRINKING DRIVER

The steps in creating a Youth Alcoholism Program in the Prince George's County Health Dept., Maryland, are described: establishing the need, developing a philosophy, formulating a program, finding the funding, and selling the program. By applying knowledge gained from the administration of an adult DWI (driving while intoxicated) program, utilizing existing resources, and charging fees, a program was developed especially designed to meet the needs of youthful alcohol abusers. The seven-week curriculum (each session approximately two hours in length) is as follows: general introduction, getting acquainted, feelings about arrest; examination of attitudes, why people do or do not drink; facts about alcohol, effects on body; exploration of problem and dependent drinking; identification of signs and symptoms of problem drinking, assessment of personal drinking behavior, influence of peers, family, decision making; drinking and driving; and personal plans, evaluation of course, final examination. All participants have an individual evaluation prior to the start of school which enables the counselor to determine the extent of the alcohol problem, to explore any other situational disturbances, and to make any immediate referrals if necessary. After the seven weeks, the client is reevaluated; and if further treatment is required, he is referred to the appropriate program. A unique feature of the program is family involvement at a meeting held prior to the beginning of classes. A modest fee is charged each client, but no client is refused service because of inability to pay. The fees are used to pay teacher/consultant salaries and to purchase materials; administrative costs are absorbed in the existing DWI program. After two years of operation, about 250 young people have received alcoholism education with 85% referred for further treatment. A recent grant from the Maryland Dept. of Transportation will allow a formal evaluation of the program.

PROJECT ADAPTS (ALCOHOL - DRIVERS AND PEOPLE - TEACHING SAFETY)

ADAPTS (Alcohol - Drivers and People - Teaching Safety), a nine-week minicourse designed for sophomores as a preliminary or concurrent class to the regular driver education classes at Newfound Memorial High School in Bristol, New Hampshire, is described. The course is designed to educate students about the abuse of alcohol and other drugs in terms of driving and social situations and to promote responsible behavior. The project was initiated two years ago with funding from the N. H. Hwy. Safety Agency. The course is activity-oriented and prevention-based. Among other objectives, it promotes understanding of self, responsible decision making, positive alternatives to alcohol and other drugs, and the reduced acceptance of inappropriate behavior. First-year evaluations on partial statistical information show positive gains through the project; further development and refinement are in process.

CHEMICAL DEPENDENCY PROGRAM FOR YOUTH AND YOUNG ADULTS

The Cumberland Farm Chemical Dependency Program (Richmond, Virginia), providing alcohol and drug abuse education and counseling to young people, is described. The program is designed to intervene in developing drug or alcohol problems. An attempt is made to afford the client a climate characterized by successful experiences and positive outlook and to acquaint the individual with his own resources and potential to discover new ways of coping with internal or environmental stresses. Focus is placed on the development of a creative approach to living and the whole-person approach is incorporated as the basis for emphasis on self-actualization. Using a multidisciplinary team approach, the following educational and counseling services are provided: evaluation, phase 1/group workshop, phase 2/structured group interaction, phase 3/group counseling, phase 4/after care/continued group therapy, individual counseling, family counseling, concerned parents group, children of alcoholics/peer group counseling, referral to supportive services, and follow-up. Any young person under the age of 25 who is a resident of the Richmond metropolitan area, who is experiencing negative consequences in his life as a result of drug or alcohol use is eligible. The nonprofit organization offers services on a sliding fee scale, based on family income.

DRUNK DRIVING AMONG YOUTH AND YOUNG ADULTS. A DESCRIPTION OF A PILOT STUDY FOR REDUCING DRINKING AND DRIVING AMONG YOUNG PEOPLE IN RICHMOND, VIRGINIA

The problem of alcohol and driving is reviewed with special reference to youth. Alcohol consumption increases the probability of crash involvement more among teenagers than among other age groups because teenagers are just learning to drive, just learning how to operate an automobile after drinking, and are doing a great deal of night driving. Youth and young adults account for a disproportionate share of both fatal and nonfatal accidents in the U.S. The ASAP (Alcohol Safety Action Project) approach is reviewed, and suggestions for its adaptation to serve the special circumstances of young drivers proposed. The ASAP approach recognizes that complicated social problems must be addressed in a comprehensive manner (enforcement, judicial, rehabilitation and treatment, evaluation, and public information and education activities). Because the lifestyle, life experiences, and value systems of youth differ markedly from those of adults, it is unwise to mix youthful and adult defendents in alcohol-related education and treatment modalities. To be effective, ASAP-Sponsored youth programs must look beyond the individual offender, addressing influences by the peer culture, the school, and the families of youth. The Richmond ASAP is described, as well as a special pilot effort developed to deal with drunk driving among youth and young adults. The Cumberland Farms, Inc. special outpatient treatment facility for youth and young adults was established in July 1978 through Richmond ASAP funds. An important feature of this program is parent involvement. A discussion is presented on the prevention of alcohol misuse by pre-driving youth, and the Richmond ASAP imitation of a clearly identified prevention program for youth who have not yet started to drive or who are just receiving their learner's permits.

THE CLASS THAT WAS DESIGNED TO TEACH - EACH ONE (DRINKING/DRIVING COUNTERMEASURE PROGRAM FOR ILLITERATE PERSONS)

The special class for the illiterate individual, established in 1972 by the DWI (driving while intoxicated) Counterattack Program in Tampa, Florida, is described. The class was structured to combat the failure experienced by the illiterate person in the regular classes of the program, which require a significant amount of reading and writing. The special program was devised to emphasize active participation, and designed to teach each student at his level of comprehension. The class is divided into four sessions with three instructors present at all times; a high student-teacher ratio was established so that each student could receive a great deal of individual attention. The first session involves exercises to allow students to experience changes in depth perception, visual field, and double vision without drinking. The second session confronts myths regarding alcohol use. Specialized drink charts are filled out by students in small groups, and reviewed with each student. The latter part of the second session is used to assign students to small groups and to assist each student in filling out a questionnare to help the student analyze his drinking problem. The third session begins with a group discussion on problem drinking, and charts are discussed in such a way that each student has an opportunity to view himself in a particular graphical representation (based on questionnaire responses). The last session reviews all materials presented, and an oral knowledge test is administered in which each student is called on randomly to answer a question. Former students of the DWI program give presentations, and films are shown during each session.

ALCOHOL COUNTERMEASURES: ALIVE AND DOING VERY WELL IN NEW JERSEY

The background and structure are described of the New Jersey Div. of Motor Vehicles, Bureau of Alcohol Countermeasures (BAC), a program mandated by state law which applies to all drivers convicted of alcohol-related traffic offenses. The BAC is the focal point of a coordinated effort within the state to reduce the incidence of drunk driving and its harmful consequences through education or rehabilitation of convicted drinking drivers, increased law enforcement, improved administration of the law, and the education of the driving population in general to a safe and reasonable standard of drinking before driving. This program is unique in the U.S. because of its mandatory nature, its low cost, its relative simplicity in design, and its pivotal location in state government. BAC was preceded by a Federally (402) funded pilot program, the Alcohol Countermeasures Project which ran from May 1972 until Apr 1977 in four counties. The BAC components are similar to those used in the Alcohol Safety Action Projects, but the BAC approach is novel in the assignment of clients to appropriate programs, in reliance on a brief education component, and in the use of community resources. The screening attempts to divide all driving while under the influence offenders into two categories for referral purposes: persons who require some kind of structured treatment for an alcohol problem, and persons who do not require such treatment but who are capable of controlling their alcohol intake when motivated. Since program inception, 25% of all referrals have been to treatment programs and Alcoholics Anonymous; roughly 75% of those referred attend the education component called the Alcohol Safety Inst. Recidivism from all BAC components is currently less than 3%.

A TEAM APPROACH TO TRAFFIC SAFETY AND ALCOHOL TREATMENT

A proposed pretrial intervention (diversion) project for the treatment of drinking drivers is depicted. The project plans to defer the prosecution of the cases while an evaluation is made to determine whether the resources of the community would be more beneficial than the court sanction. The proposed approach is to use the Community Resources Management Team (C.R.M.T.) concept, under which the probation counselor/officer will share his case load with a team of six officers. The counselor will develop a comprehensive file of community resources related to his area of expertise. The team concept frees the counselor to establish relationships with other agencies and to determine what type of client will benefit from the available services. The C.R.M.T. will consist of a senior officer, two clerks, three junior officers, and two paraprofessionals. The team will supervise a case load of approximately 400 clients. One of the officers will specialize in mental health, one in alcohol abuse, and the third in employment, education, and vocational training. The senior officer will be responsible for group correlation. The paraprofessionals will be responsible for the supervision of the paperwork cases, estimated at 45%. The total pretrial intervention project should consist of the diagnostic and screening section, data control section, restitution section, violation section, C.R.M.T., and group therapy. The project brings together those agencies which ordinarily operate separately to act as a combined force, developing avenues to accomplish objectives beneficial to the community and the clientele.

THE NEW YORK STATE ALCOHOL AND DRUG REHABILITATION PROGRAM

The background, operation, and evaluation are described of the New York State Alcohol and Drug Rehabilitation Program, commonly referred to as the Drinking Driver Program (DDP). The DDP, fully operational since 1 Oct 1975, was developed by incorporating the most successful approaches to dealing with the drinking driver evidenced in Alcohol Safety Action Project efforts and in experimental programs conducted in New York State. The principal objectives of the program are to reduce alcohol-related (A/R) accidents and incidents, to offer alcohol rehabilitation services, and to stimulate prosecution of A/R driving charges. By design, the DDP allows about 95% of all motorists convicted of A/R charges to enter a program of education and rehabilitation. While participation in the program is voluntary, courts have been encouraged to conditionally discharge motorists into the program. In essence, the motorist is not imprisoned and generally not fined or put on probation, under the condition that he attend and satisfactorily complete the DDP. The program consists of a 16-hour, seven-session course of learning and discussion, which addresses drinking and driving behavior and its impact on the traffic system as a whole, and includes self-analysis of drinking behavior. Some motorists are referred to professional counselors and rehabilitative programs if during the classroom phase, the instructor determines that a motorist may be in need of alcoholism treatment. All costs of the program are borne by the participant. Evaluation studies have shown that a group of DDP drivers had a significantly higher rate of conviction during the 18 months prior to program participation than a total driver population group during a concurrent period, but had a significantly lower conviction rate in the 18 months subsequent to DDP participation. Although both groups had a statistically significant reduction in accidents from the one period to the other, the DDP group still had a post-treatment accident rate twice as high as the driver population sample.

THE EFFECTS OF ALCOHOL ON THE DRIVER'S DECISION-MAKING BEHAVIOR. VOL. 2: APPENDICES. FINAL REPORT

Two experiments were designed to investigate the effects o alcohol on driver decision making as opposed to driver contro capability. A laboratory study was made involving a complex interactive driver simulator, followed by a field validation experiment employing an instrumented car and interactive tes course which duplicated many driving simulator tasks and conditions. The research was designed to determine whether alcohol affects the driver's willingness to accept risk, or whethe alcohol merely deteriorates his perceptual and psychomoto properties, leading to unavoidable increases in risk taking tha cannot be compensated for. The results of the two experiment are quite consistent. Risk taking increased in a dose-respons relationship with blood alcohol concentration as measured i increased accidents and traffic tickets, and the accident result are consistent with real-world epidemiological data. Decisior making analysis indicated that the increased risk taking wa caused by degraded perceptual and psychomotor capabilities, not increased acceptance of risk.

REGIONAL WORKSHOPS ON BICYCLE SAFETY: PRESENTATIONS, PARTICIPANT PROBLEMS, PROGRAMS IDEAS, AND RECOMMENDATIONS. FINAL REPORT

At ten regional workshops on bicycle safety, Feb-Apr 1978, 439 bicycle safety professionals met to discuss ongoing projects, problems, ideas, and recommendations for improvements. The workshops were sponsored by the National Hwy. Traffic Safety Administration and the Consumer Product Safety Commission. Abridged staff presentations (by Urban Scientific and Educational Res, Inc.) cover the following areas: background, comprehensive safety program planning, six major accident groups, education concepts, implementation theory, program cost, facilities concepts, and evaluation. A state of the art of bicycle safety is formulated based upon the common programs in the U.S., and comment is given on rare and innovative programs. Recommendations to Federal, state, and local governments are presented, with brief descriptions of the intent and rationale for each. Appended are an index of workshop materials, and a participant list with short bicycle interest biographies as submitted. Education programs were widely criticized; evaluation of old and development of new approaches were recommended. It was suggested that bicyclist behavior may change positively after enforcement, and that enforcement requires more effort than is now exerted. Evaluation of facilities projects for safety impact was advocated as a means to assist in developing a methodology for prioritizing facilities projects. It was found that facilities were generally directed only at the overtaking accident; cost considerations suggest this approach will not make a substantial impact on bicycle safety. New facilities approaches to reduce bicycle/motor vehicle conflict at intersections were recommended. Effective cycling or on-the-road bicycle education received considerable attention, and demonstration programs, with evaluation and cost-effectiveness analysis, were recommended.

MANUFACTURER'S POLICIES CONCERNING AVERAGE FUEL ECONOMY STANDARDS. FINAL REPORT

A preliminary analysis is provided of U.S. automobile manufacturers' probable responses, and of issues bearing on their decision making for meeting average fuel economy standards for the 1981 through 1985 model year passenger automobiles. Alternative schedules for fuel economy standards are considered. Manufacturers' options, both technological and nontechnological, are discussed for meeting the standards. Exogenous factors that bear on standards implementation (national economic climate, energy policy and conservation, factors bearing on costs of ownership and operation, and those bearing on transportation and travel demand) are examined. The likely overall strategy of the automakers in compliance efforts, and the probable strategies of the individual companies (American Motors Corp., Chrysler Corp., Ford Motor Co., and General Motors Corp.) are discussed.

BASELINE TEST OF COMPACT VEHICLE SIDE STRUCTURE, 25 MPH, 60 DEGREE IMPACT, TORINO-TO-VOLARE, TEST NO. 1

A baseline test was conducted as part of an 11 crash and 1 crush test program to evaluate the improvement in side impact crashworthiness of a compact automobile incorporating improved front door structural characteristics. Test No. 1, run at 25 mph at a striking angle of 60 degrees, involved a 1975 Ford Torino as the bullet vehicle and a 1976 Plymouth Volare as the target vehicle. Presented are a crash test summary, before and after photographs, lists of camera locations and intrusion measurement locations, interior and exterior damage measurements, instrumentation locations, dummy positions and injury criteria values, and electronic data in plotted form.

IMPACT TEST OF COMPACT VEHICLE WITH MODIFIED SIDE STRUCTURE, 25 MPH, 60 DEGREE IMPACT, TORINO-TO-VOLARE, TEST NO. 3. FINAL REPORT

A test was conducted as part of an 11 crash and 1 crush test program to evaluate the improvement in side impact crashworthiness of a compact automobile incorporating improved front door structural characteristics. Test No. 3, run at 25 mph at a striking angle of 60 degrees, involved a 1975 Ford Torino as the bullet vehicle and a modified 1976 Plymouth Volare as the target vehicle. Volare modifications included a heavier door beam, stronger beam-to-door connections, and tabs for locking the door structure into the sill. The modified vehicle showed significant improvement in intrustion and door velocity compared to baseline tests. Presented are a crash test summary, before and after photographs, lists of camera locations and intrusion measurement locations, interior and exterior damage measurements, instrumentation locations, dummy positions and injury criteria values, and electronic data in plotted form.

CHILD RESTRAINTS. ISSUE PAPER

The issue of child restraints is addressed, and the National Hwy. Traffic Safety Administration's position on state laws regarding this issue is presented. States are encouraged to enact legislation to require special protection for young children. Since the special vulnerability of young children can be reduced only by responsible adult action, each state is encouraged to enact legislation that will adopt the Dept. of Transportation's performance standard (Federal Motor Vehicle Safety Standard 213) for child passenger protective devices, encourage proper conformance to manufacturers' instruction on proper usage, and require the use of such devices for child passengers in a motor vehicle. Copies of an article by Kenneth W. Heathington on the first six months of Tennessee's child restraint law, from Traffic Safety (Nov 1978), and of child restraint legislation enacted in Washington State are provided.

NONRESIDENT VIOLATOR COMPACT OF 1977. ISSUE PAPER

The issue of the Nonresident Violator Compact (NVC) of 1977 is addressed, and the National Hwy. Traffic Safety Administration's position on state NVC adoption is presented. The NVC should be adopted by all states for several reasons. Police are able to devote more time to highway patrol, surveillance, and apprehension since they are not burdened with violator processing procedures. Court revenues are increased since nonresidents cannot ignore a party state's citation without facing a driver license penalty at home. The number of "failure-to-appear" cases has decreased in those states where the NVC has been adopted. Motorists' delay and/or inconvenience is comparable for resident and nonresident violators. Copies of model enabling legislation and model compact are provided.

55 MPH MAXIMUM SPEED LIMIT RADAR DETECTION DEVICES. ISSUE PAPER

The issue of the use of 55 mph maximum speed limit radar detection devices by motorists is addressed, and the National Hwy. Traffic Safety Administration's position on state laws regarding this issue is presented. The only purpose for a radar detection device is to avoid apprehension for violating the speed limit, and law enforcement agencies strongly oppose the manufacture, sale, possession, and use of these devices. State enforcement agencies should make individual analyses of the extent to which radar detectors adversely influence speed limit compliance or enforcement tactics and costs in the state, and, on the basis of these analyses should recommend appropriate state legislative action, including the enactment of statutes prohibiting their possession and/or use by motorists. Truck and bus companies should also prohibit the use of radar detectors by their drivers. Copies are provided of Section 46.1-198.1, Code of

Virginia; Connecticut regulation of the Commissioner of Motor Vehicles, Section 14-1-137; and Article 25, Section 16 of the District of Columbia police regulations, all prohibiting the use of radar detection devices.

ALCOHOL COUNTERMEASURES: ILLEGAL PER SE AND PRELIMINARY BREATH TESTING LAWS. ISSUE PAPER

The issue of illegal per se and preliminary breath testing laws is addressed, and the National Hwy. Traffic Safety Administration's position on these laws is presented. States should be encouraged to adopt the preliminary breath test and illegal per se laws since they increase the number of drinking driver arrests and the conviction rates for arrests. The increased scientific/research support for the breath alcohol test as an objective measurement of driver impairment, and the rapid improvement in breath alcohol measurement technology and chemical testing programs have made possible the adoption of these laws. Copies of a Uniform Vehicle Code (UVC) model law (illegal per se) and a preliminary breath test-implied consent model law (which would amend UVC Section 6-205.1) are provided.

GENERAL SAFETY BELT USAGE. ISSUE PAPER

The issue of general safety belt usage is addressed, and the National Hwy. Traffic Safety Administration's position on state laws regarding this issue is presented. Necessary factors in mandatory seat belt usage legislation include a monetary penalty for noncompliance, continuous enforcement carried out whenever a police officer stops a motorist for another violation, and a public information program concerning the benefits of using safety belts. States are encouraged to enact legislation that will require the use of safety belts provided the effective date of the law is established so as to permit: adequate time to develope public awareness, understanding, and voluntary compliance; and the orientation and training of the personnel responsible for implementation. Tabulated information is presented on the effect of safety belt usage laws worldwide. A copy of a model safety belt use law is provided.

URBAN PEDESTRIAN SAFETY. ISSUE PAPER

The National Hwy. Traffic Safety Administration's position on state laws regarding the issue of urban pedestrian safety is presented. Efforts must be made to improve the uniformity of state pedestrian laws. City, county, and state authorities must be able to identify their specific pedestrian problems and plan programs to impact them. Pedestrian accident data must provide a reasonably accurate assessment of the relative magnitude of the pedestrian accident types. The state and local traffic record system should be based on data provided through accident investigation and reporting. To facilitate these programs, a single state agency should have primary administrative authority and responsibility for pedestrian safety. The state and its political divisions should establish policies and directives that bring about countermeasure activity on a multidisciplinary basis. The laws and ordinances should be in reasonable conformity with appropriate chapters and sections of the Uniform Vehicle Code (UVC) and Model Traffic Ordinance, with flexibility allowed for the adoption of laws outside the UVC which will enhance pedestrian safety. Copies of two model pedestrian ordiances (Bus Stop and Ice Cream Truck) are provided. Seven of the 30 specific pedestrian accident types are listed; these seven types account for about 60% of all urban pedestrian accidents: dartout, intersection dash, vehicle turn/merge (attention conflict), multiple threat, bus stop related, ice cream vendor truck, and backing.

STUDY AND TEST TO CONFIRM AUTOMOBILE DRIVETRAIN COMPONENTS TO IMPROVE FUEL ECONOMY. VOL. 2. THE DRIVETRAIN DESIGN PROCESS WITH AN AUTOMATIC TRANSMISSION. INTERIM REPORT

The key thought processes are outlined that are used by the drivetrain designer in matching an engine to a given vehicle with specific performance goals in mind. For those uninitiated in this aspect of automotive design, valuable insight is provided into the compromises that must be made among acceleration, gradeability, and top speed. Also presented is a method by which the performance of any modern torque converter may be approximated with accuracy, when only the stall torque ratio and diameter are known. These two parameters can be used to generate torque converter maps that almost duplicate actual maps for torque converters of any modern manufacturer, and greatly facilitate computer simulation.

SEAT BELTS: 1949-1956. FINAL REPORT.

The history of seat belt use is reviewed for the period 1949-1956. The aircraft industry was responsible for the development of seat belts and much of the early research relating to injury, deaths, and accidents. Early advocates of belts included safety researchers, engineers, and doctors. In 1955, there were a number of barriers to the adoption of belts, including poor design, high cost, installation problems, the lack of a sales effort or consumer information campaign, and the lack of a consistent set of standards, as well as misconceptions held by many consumers. By 1955, seat belts were at the center of a hotly contested behind-the-scenes controversy over safety in the automobile industry. In this struggle, Ford played the role of a strong advocate for safety and seat belts; GM was an adversary. Ford undertook a program, the "Safety Campaign," in order to sell various safety features on its 1956 models. The campaign was short-lived, the industry claiming that safety did not sell. However, there is much to suggest from Ford's experience that safety does indeed sell. Ford's reversal on the safety program set back the seat belt movement for a number of years, and may be partly responsible for bringing about government regulation of the industry.

DEVELOPMENT OF A LOW COST PORTABLE FLUOROMETRY TECHNOLOGY AND QUANTIFICATION OF CANNABINOIDS IN BODY FLUIDS. FINAL REPORT

Technology was developed for determining delta-9-tetra hydrocannabinol (I) and its major metabolite 11-nor-delta-9-tetrahydro- -cannabinol-9-carboxylic acid (II) in human blood plasma utilizing high pressure liquid chromatography-ultraviolet detection. The methods were found to be capable of determining 10 ng (nanograms) of I or II in one ml of human plasma. A third type of assay method was developed for identifying in human saliva one of the major constituents of marijuana, cannabinol (III). Results indicated that III photolytically converted to a highly fluorescent compound in the absence of air. Using this technique, a limited study of marijuana smoker's saliva and saliva from non-marijuana smokers to which I and III had been added was conducted. This study demonstrated that 1 ng/ml of III can be detected in saliva.

DRIVER VISIBILITY QUALITY: AN ELECTRO-OPTICAL METER FOR IN-VEHICLE MEASUREMENT OF MODULATION TRANSFER (MTF). FINAL REPORT

In order to provide a practical means for developing and monitoring standards of driver visibility quality, an electro-optical modulation transfer function (MTF) meter was designed and delivered to the National Hwy. Traffic Safety Administration. Tests were conducted with Landolt ring targets to relate human vision to meter readings, under various types of optical degradation (windshield fogging, icing, dirt film, etc.); there was excellent agreement between meter readings and visual test measures, confirming that the visibility quality meter (VQM) can determine whether visibility quality meets minimum requirements. The VQM is a rugged and simple solid-state device with an oscilloscope display of image luminance cross-section; image contrast values are read directly from the display for determination of MTF (i.e. contrast transmittance). The large body of visual contrast-sensitivity data available in the literature can be directly related to VQM readings, thus providing visibility standards for targets of a given size, shape, distance, luminance, and viewing condition. Further research with driving-specific visual tasks is required to directly link the VQM and driver visibility requirements. Significant findings include: a relatively simple optical meter can be used for in-vehicle measurement of contrast degradation and optical distortion; since the MTF's in question are decreasing monotonic functions of spatial frequency, it is sufficient to test at just one spatial frequency representing finer detail to ensure adequate visibility for all detail larger than the test frequency; driver visibility is limited more often by contrast degradation than by inadequate resolution, since many of the driver's visual tasks involve relatively very large objects; the MTF for veiling luminance is equal at all frequencies, permitting very simple measurement.

STATE PMVI (PERIODIC MOTOR VEHICLE INSPECTION) PROGRAM EVALUATION. FINAL REPORT

Of the three objectives of the program, the most important was to implement and critique the methodology for evaluating periodic motor vehicle inspection (PMVI) programs developed under Contract DOT-HS-5-01159. Full-scale administrative and field evaluations of PMVI programs in Virginia and New Hampshire were made, involving passenger cars only. A second objective was to perform field evaluations of brake component condition, comparing brake condition in states with and without wheel pull requirements. A total of 3533 vehicles was inspected in Virginia and New Hampshire (wheel pull), and Maine and Maryland (no wheel pull). The availability and condition of seat belts were analyzed in 3100 of the vehicles inspected. A third objective was to design an experiment for direct measurement of the impact of PMVI on overall vehicle condition. Alternative designs for such an experiment are discussed, including controlled experiment, non-equivalent control group, before/after, and interrupted or multiple time series. The last mentioned design is recommended.

MOTORCYCLE HANDLING. VOL. 2: TECHNICAL REPORT. FINAL REPORT

Analytical and experimental studies of the handling response and performance of motorcycles are reported. Five instrumented example vehicles were used. Steady turn, single lane change, cornering and braking, and cornering and accelerating tests were accomplished. Test procedures and measures are presented, together with subjective evaluations. Oscillatory behavior involving weave and wobble motions was investigated. The effects of adding load, changing operating conditions; and modifying vehicle configuration are shown. Braking tests were made with a motorcycle fitted with a prototype antilock brake system, and the results show markedly superior performance on wet (low skid number) surfaces. Linear and nonlinear digital computer simulations of motorcycle response and performance are described and demonstrated.

EVALUATION OF THE MULLARD/TRRL (TRANSPORT AND ROAD RESEARCH LABORATORY) ANTILOCK BRAKE SYSTEM. FINAL REPORT

Full-scale braking tests are reported for a Norton 850 motorcycle fitted with a prototype antilock brake system on the front and rear wheels. The system was designed by Mullard, Ltd. (U.K.) and has undergone development and demonstration work at the Transport and Road Res. Lab., Crowthorne, England. The tests included straight-line braking and braking in a turn, on both dry and wet surfaces. Various braking methods were used in addition to the antilock system, including open-loop (with brake force limiters) and closed-loop control by an expert test rider. On low-coefficient wet surfaces, the antilock system gave braking performance which was significantly better than that which could be achieved by either an expert rider or suitably-tuned, open-loop braking procedures. A description of the motorcycle data acquisition system is appended.

DRIVER-VEHICLE EFFECTIVENESS MODEL. VOL. 1: FINAL REPORT

Work is described which involved refinement and expansion of the Driver-Vehicle Effectiveness Model (DRIVEM) and implementation of model software on a computer facility designated by the National Hwy. Traffic Safety Administration (NHTSA). DRIVEM is a Monte Carlo simulation model intended for use by NHTSA to evaluate alternative vehicle subsystems or effects of legislative actions proposed to reduce the probability and severity of highway traffic accidents. Candidate DRIVEM applications were structured around Federal Motor Vehicle Safety Standards (FMVSS) requirements, in particular the 100 series (pre-crash) standards. Based on FMVSS review and discussions with NHTSA, candidate areas of application selected were displays and controls, rearview mirrors, windshield clearing system and pillar design, vehicle exterior lighting, reflecting surfaces, service brakes, tires and rims, and steering and suspension. Eleven scenarios representing potential accident situations to be simulated were developed based on a review of accident literature, and the relevance of these situations to DRIVEM applications was evaluated. Work on the model development task was concentrated in component areas of driver modeling and vehicle modeling. The DRIVEM digital program was implemented in FORTRAN and demonstrated in a sample application to illustrate user procedures. Recommended areas for further work to improve and verify the predictive capability of DRIVEM and its utility to NHTSA are model applications experience, expert review and critique, and validation studies.

DRIVER-VEHICLE EFFECTIVENESS MODEL. VOL. 2: APPENDICES. FINAL REPORT

Detailed flow charts and FORTRAN program listings of the main program and subprograms for the Driver-Vehicle Effectiveness Model (DRIVEM) are provided. Sample input and output of a representative application of the DRIVEM simulation are presented; the scenario simulated is the subject vehicle (driver-vehicle system) following in the presence of oncoming traffic under nighttime conditions with a decelerating vehicle directly ahead. Detailed equations are presented for each of four vehicle models (6-, 3-, 2-, or 1-degree of freedom). Probability expressions from corresponding logical expressions for a maneuver decision model are derived, as well as probabilities of adjacent vehicles occupying each of various safe-maneuvering regions. Nominal values for DRIVEM parameters and variables are given, as well as the basis for the nominal data. DRIVEM is a Monte Carlo simulation model intended for use by the National Hwy. Traffic Safety Administration to evaluate alternative vehicle subsystems or effects of legislative actions proposed to reduce the probability and severity of highway traffic accidents.

VEHICLE ANTI-THEFT SECURITY SYSTEM DESIGN. VOL. 2: FINAL TECHNICAL REPORT

A vehicle theft survey was conducted, consisting of a literature search and interviews with a wide range of experts including law enforcement officials, insurance personnel, automobile manufacturers, and automobile thieves. The data, which include up-to-date statistics on theft rates, motives, methods, and costs, were analyzed to identify and rank the most important criteria for anti-theft systems. Based on these criteria, a conceptual design study was conducted to identify anti-theft system concepts. From several promising system concepts, a remote steering lock coded by means of a keyboard in the passenger compartment was selected as optimum for a test system. The system was fabricated and installed in a test vehicle. Prior to the installation of the improved system, the factory-equipped, locked vehicle was mobilized by an amateur test subject in 50 seconds. The improved system resisted the efforts of a retired professional auto thief who gave up the effort after nearly 17 minutes (the design goal being 10 minutes). The ultimate consumer price increase to cover the system is estimated to be between $17 and $36, a range well below the design goal of $50 (based on expected average savings in theft costs over the life of the vehicle). As a result of the survey and the design program, a modified safety standard based on minimum time-to-defeat is recommended as the most straightforward and least design-restrictive approach. An alternative, based on limited accessibility of the vulnerable components, is also recommended if subjective compliance testing must be avoided, although this alternative is inherently more design-restrictive.

RAILROAD RETARDER NOISE REDUCTION. STUDY OF ACOUSTICAL BARRIER CONFIGURATIONS. FINAL REPORT

Field measurements of noise were made near a railroad retarder system without barriers and with acoustical barriers of various configurations. The configurations tested included acoustically reflective and acoustically absorptive barriers with heights of 4 ft to 12 ft and lengths extending from 0 ft to 22 ft beyond retarder entrance and exit. Two of the 12 ft high barriers were also tested with 1 ft inward projecting acoustical panel lip along the top. It was found that the absorptive barriers reduced retarder noise from a few decibels inside the barriers to as much as 25 dB at 100 ft from the retarder on the system centerline perpendicular to the tracks. Reflective barriers increased noise inside the barriers and at points outside, but near open ends, of the barriers; the reflective barrier noise reduction on the perpendicular centerline was limited to about 16 dB. Retarder noise was concentrated in a frequency range between 2 kHz and 3 kHz. It is concluded that to date no innovations, improvements or inventions have been made and that currently available schemes for predicting acoustical performance of a barrier do not yield accurate predictions for railroad retarder application.

SAFETY RELATED RECALL CAMPAIGNS FOR MOTOR VEHICLES AND MOTOR VEHICLE EQUIPMENT, INCLUDING TIRES, REPORTED TO THE NATIONAL HIGHWAY TRAFFIC SAFETY ADMINISTRATION BY DOMESTIC AND FOREIGN VEHICLE MANUFACTURERS, JANUARY 1, 1979 TO MARCH 31, 1979

This tabulation of safety defect recall campaigns of motor vehicles and equipment includes the National Hwy. Traffic Safety Administration identification number, date of company notification, make, model, model year, number of pages on file, number of vehicles recalled, and a brief description of defect and manufacturer's corrective action for each recalled product. Summary tabulations list number of recall campaigns and number of vehicles involved for domestic, foreign, equipment, and tire manufacturers reporting. The status of domestic and foreign campaigns completed as of 31 Mar 1979 is also tabulated. Among the vehicles involved in safety recall campaigns for this period are passenger cars, trailers (livestock, travel, camping), light, medium, and heavy duty trucks, motorhomes, transit coaches, motorcycles, mopeds, semi trailers, tank trailers, four-wheel-drive vehicles, and school buses. Equipment involved in recall campaigns includes tires, gasoline filters, bumper jacks, travel trailer doors, and telesopic hoists.

DESIGN FOR A NATIONAL EXPOSURE DATA SYSTEM (NEDS): RECOMMENDED FEATURES AND PROPOSED PILOT METHODOLOGICAL STUDIES. FINAL REPORT

In conjunction with the National Accident Sampling System (NASS) which is being established by the National Hwy. Traffic Safety Administration to collect data on a nationally representative sample of accidents, there is a need for corresponding data on exposure to the risk of accident so that reliable accident rates can be determined. An effort was undertaken to design a National Exposure Data System (NEDS) and to plan a pilot test of this design. After extensive review of previous research studies and evaluation of the various design alternatives available, a number of features of the recommended design were established. The NEDS should involve a household interview survey in which selected drivers are asked to provide information about all driving trips made on one or more predesignated days, the location being in the same primary sampling areas used for the NASS. Not enough information was found in past studies to permit recommending the single, most cost-effective house hold data collection procedures. It is proposed that a pilot methodological study be carried out over 12 months to provide the essential data base for this decision. Evaluation criteria will include cost, completeness of trip reporting, response rates, coverage of the relevant population, accuracy of trip distance data, and completeness of reporting other trip variables.

STATE LAWS ON PROBATIONARY LICENSING AND LICENSING OF MINORS

The state laws are reviewed on probationary licensing as they relate to all new licensees, especially to minors. Also examined are laws that affect minors but not as part of a probationary licensing scheme. The Uniform Vehicle Code and the relevant state laws are reviewed to ascertain the mechanisms by which probationary licensees and minors are identified, the restrictions on driving that are imposed, and the remedial actions that are administered. Twenty states place first-time licensees on probationary status (13 applying to minors and 7 to all original applicants). Although 31 states do not have probationary licensing laws, 16 states have laws affecting minors similar to probationary licensing. The most common age below which a probationary term is required is 18. Eleven states terminate the probationary period upon reaching the designated age, and nine states specify a set term. Six states have discretionary extension of the term based on driving record, and three will extend the period following license suspension or revocation. Probationary status is designated on drivers' licenses by color or design or use of profile rather than full-face photograph. Minors are similarly designated in some states. Two states restrict the driving time of probationary licensees to specific hours. Revocation of probationary licenses varies in terms of number of violations. Twenty-six states have laws relating to the licensing of minors in the areas of age identification, driving restrictions, and remedial action. Six states restrict driving time of minors not accompanied by an adult licensee. Special license withdrawal provisions for minors exist in ten states; only one state requires a minor's attendance at a driver improvement program.

CORPORATE STRATEGIES OF THE AUTOMOTIVE MANUFACTURERS. VOL. 1: EXECUTIVE SUMMARY OF CONCLUSIONS, STRATEGIC ISSUES. FINAL REPORT

Strategic issues involving eight domestic and foreign automotive manufacturers (American Motors Corp., Chrysler Corp., Ford Motor Co., General Motors Corp., Toyota Co., Nissan Motor Co., Honda Motor Co., and Volkswagen A.G.) are described and examined. The following three future scenarios involving a major regulatory program and an environmental counterforce are explored: the impact of a possible economic recession on automaker ability to comply with existing and possible future fuel economy standards, the impact of product liability trends on automaker ability to comply with existing restraint legislation (passive restraints as mandated by Federal Motor Vehicle Safety Standard 208), and emissions control standards and the impact of platinum group metals (catalyst) supply. A description of pricing in the automobile industry is presented and an examination made of the marketing practices of the automobile industry, including a description of the decision-making process in each automobile company. It is concluded that the regulatory process is likely to lead to an increasing concentration of market share by one or two of the largest companies. The cost impact of regulatory standards is likely to create annual price increases that will exceed rates of inflation or growth in consumer income. Efforts by the automakers to counter major consumer resistance to new vehicle types, price increases, or fuel-economy-related product mix goals of the American manufacturers may result in a shrinking of profit margins and internal investment flows. Even a minor recession in the next eight years is likely to destroy the abilities of Chrysler and American Motors to maintain their announced investment programs to meet existing regulations. The length of the product planning cycle has stretched to five or more years by the organic character of change required to meet regulations. A considerably higher frequency of product liability suits against automakers concerning passive restraints is very likely. It does not appear likely that technical or political problems will interfere with the ability of automakers to meet 1981 emission standards.

CORPORATE STRATEGIES OF THE AUTOMOTIVE MANUFACTURERS. VOL. 2: STRATEGIC HISTORIES. FINAL REPORT

Strategic histories, beginning in 1945 and projected through 1985, are presented for eight domestic and foreign automotive manufacturers (American Motors Corp., Chrysler Corp., Ford Motor Co., General Motors Corp., Toyota Motor Co., Nissan Motor Co., Honda Motor Co., and Volkswagen A.G.). Each history is presented in three "episodes," usually 1945 to 1960 (VW, 1948-1968, 1969-1975), 1961 to 1975, and 1976 to 1985. The histories were developed from a wide variety of published sources. After drafts of the histories were completed, they were submitted to the company managements for review of factual accuracy. External influences, major strengths and weaknesses, assumed mission, assumed objectives, and strategies of each company are described for each time frame.

CORPORATE STRATEGIES OF THE AUTOMOTIVE MANUFACTURERS. VOL. 3: PANORAMA OF SELECTED ECONOMIC AND OPERATING INFORMATION. FINAL REPORT

Some of the principal historical trends in the U.S. automotive industry are reviewed. Some basic factors about the operating economics of the auto industry are outlined to include the following: output capacity, relative capital intensiveness, the manufacturer-dealer relationship, collective bargaining, multinationalism, innovation and its relationship to research and development, capital structures, product life cycles, vertical integration and vendor relations, and miscellany. Primary demand for passenger cars is reviewed in terms of unit sales and market shares (1946-1977), key national economic indicators (1945-1977), passenger cars in operation (1946-1976), average age of passenger cars, and Consumer Price Index for new and used cars (1960-1977). Primary demand for light trucks is reviewed in terms of unit sales by class and market shares (1947-1977), and unit sales by body type (1966-1976) and market shares (1975-1976). An outline of corporate economics covers manufacturer financial data and management performance, and employment for the period 1945-1977. Marketing is reviewed in terms of new car dealership data, and media advertising expenditure for the period 1956-1977. Attached are an excerpt from the automotive industry section of a book on the structure of American industry, and articles in Fortune about consumer demand for pickups and vans, and a Ford dealership in Ohio.

DPMAS (DRIVER PERFORMANCE MEASUREMENT AND ANALYSIS SYSTEM) UTILIZATION. VEHICLE PARAMETER IDENTIFICATION. FINAL TECHNICAL REPORT.

The Driver Performance Measurement and Analysis System (DPMAS) was evaluated by using it to support the development and validation of a simplified model of automobile lateral dynamics. The DPMAS is a sophisticated instrumented vehicle developed by the National Hwy. Traffic Safety Administration for use in driver performance research. Equations describing free body motion of an automobile in inertial space are so complex as to be unusable in a practical sense. Even with simplifying assumptions to derive a set of quasilinear equations, a total of 46 parameters must be measured to define vehicle dynamics. A second order model has been developed which is useful providing the transfer function for the vehicle is known. In this study, a method was developed for estimating the transfer function coefficients for the second order model from data taken from the DPMAS. The model was shown to agree well with field data. Based on these results, it is concluded that a very simple measure, based on the damping ratio of the second order roots of the model, can be used as a measure of relative vehicle stability which is a function of both speed and lateral acceleration.

OPTIMUM FREQUENCY OF INSPECTION. FINAL REPORT (BRAKE SYSTEM COMPONENTS)

A study was undertaken to develop a means for determining the optimum frequency for inspecting brake system components in order to minimize the probability of their being defective in the vehicle-in-use (VIU) population. The approach was to analyze the latest available brake inspection data and to use these results along with previously developed analytical techniques (Optimum Brake Inspection Plan, Contract No. DOT-HS-6-01383) to determine the optimum frequency of inspection. Data were collected and analyzed from a group of states participating in experimental wheel-removal brake inspection programs. Data from most of the participating states were not usable, but analysis of usable data from Florida, New Mexico, and Oklahoma revealed that the results were essentially the same as those obtained from an analysis of the Dept. of Transportation's VIU data base. The analysis also revealed that it was possible to merge the state data to update the VIU data base. The results of this study indicate that the Optimum Brake Inspection Plan developed for the earlier contract can likewise be utilized as a plan for specifying the optimum frequency of inspection for brake system components. The plan specifies inspecting brake fluid every six months on all cars, using brake tester on all cars in conjunction with the brake fluid level test, inspecting all front wheel brake components every six months beginning at a vehicle age of 18 months, and inspecting the front brake hose every six months beginning at vehicle age of three years. Recommendations for future study concern the use of the Criticality Index approach to designing optimum inspection programs.

TECHNIQUES FOR PREDICTING HIGH-RISK DRIVERS FOR ALCOHOL COUN- TERMEASURES. VOL. 2. USER MANUAL. FINAL REPORT

This user manual is designed to aid the alcohol program administrator in his decisions concerning implementation of countermeasures to selected individuals or small groups of drivers. The manual shows how the predictor models developed as described in Vol. 1 can be used to predict the probability of a future alcohol-related crash for six high-risk groups of drivers (young males, 16-20 years old; males, 21-24 years old; persons recently divorced; persons recently released from prison; persons recently convicted of driving under the influence; and persons accumulating three or more traffic violations in a 5-year period). The user manual contains information on the inputs and outputs of the predictor models, information on the cost and effectiveness of potential countermeasure programs, and a method for conducting an economic analysis of a chosen countermeasure applied to a target group. Also presented is a brief overview of evaluation techniques and problems as they relate to trial alcohol countermeasure programs. Information concerning development of the predictor models, sample forms for use in the economic analysis, and a program listing for the computerized economic analysis are appended.

FEASIBILITY OF DEVELOPING TRAINING PROGRAMS DESIGNED TO IMPROVE DEFICIENT DRIVER FACTORS. VOL. 1: A REVIEW OF EXISTING DATA BASES AND RECOMMENDATIONS FOR FUTURE DATA COLLECTION. FINAL REPORT

The feasibility was determined setting driver education program instructional objectives from existing accident data, and recommendations were made for appropriate National Hwy. Traffic Safety Administration action to define such instructional objectives. It was found that, although much accident data can be used to identify driver-oriented traffic safety problems, existing data are not adequate for setting comprehensive instructional objectives and priorities. A suitable dataset for these purposes would permit the identification of actions that drivers might have taken to prevent accidents, and would be nationally representative. The authors recommend a special study under the National Accident Sampling System as the appropriate means of collecting the desired data. Vol. 1 includes results of a literature review, a detailed definition of the information required to set instructional objectives, a review of existing data bases, a plan for collecting additional data, and a plan for incorporating new data and new instructional objectives into driver education programs. Appended supporting materials include a bibliography and sample reviews of existing multidisciplinary accident investigation cases.

FEASIBILITY OF DEVELOPING TRAINING PROGRAMS DESIGNED TO IMPROVE DEFICIENT DRIVER FACTORS. VOL. 2: IDENTIFYING ACCIDENT AVOIDANCE BEHAVIORS: A GUIDE FOR ACCIDENT INVESTIGATORS. FINAL REPORT

A manual of procedures is provided for investigating accidents in order to identify accident-avoidance behaviors. After these behaviors have been identified, they will be analyzed by researchers to develop training objectives for driver education courses. The scope of avoidance behaviors encompasses the entire accident sequence, including predisposing, preventive/defensive, evasive, impact, and post-accident phases. Types of accidents are classified as single vehicle, intersecting vehicle, overtaking vehicle, converging vehicle, oncoming vehicle, pedestrian, and miscellaneous. Drivers are classified as burdened and privileged. General procedures for accident investigation are outlined, as are steps in identifying avoidance behaviors.

SAFETY SYSTEMS OPTIMIZATION MODEL (SSOM). VOL. 2. METHODOLOGY AND OPTIMIZATION RESULTS. FINAL REPORT

A generalized methodology has been developed for mathematically optimizing simulated vehicle crash performance for a wide range of realistic accident encounters. The methodology utilizes approximating functions, derived from multi-degree-of-freedom dynamic simulations, to calculate vehicle and occupant dynamic responses in a large number of simulated collisions. Biomechanical relationships are used to convert the occupant responses into estimates of injury, which are weighted and summed for all the simulated accidents to produce an overall measure of crash performance. An optimization algorithm systematically searches selected simulated vehicle design variables for the set which minimizes the weighted sum of injuries within practical limits set by the analyst. As an example of the application of the methodology, a computer program was developed to optimize the crash performance of a simulated 3000 lb vehicle operating in the mid-1980's traffic environment. Two example optimization runs, for belt and air bag restraints, have been conducted. In this current effort, the optimization methodology, which was developed by Ford in Phase 1 of the Research Safety Vehicle program, was refined and extended to produce the current optimization model. The methodology and model refinements are documented, and example model results presented, as well as recommendations for further development of the model.

REHABILITATION EFFECTIVENESS FOR SAFE PROJECT DRIVERS RECEIVING DEFENSIVE DRIVING COURSE TRAINING. A SUPPLEMENTAL EVALUATION REPORT. FINAL REPORT

The effectiveness of three versions of the Defensive Driving Course (DDC) was evaluated within the context of referral to treatment from Seattle's Special Adjudication for Enforcement (SAFE) system. The SAFE system has in common with the administrative adjudication approach the elimination of a formal courtroom appearance, and it is unique in that a para-judicial (magisterial) system is employed. A magistrate may refer a traffic offender to a driver improvement analyst for diagnosis and/or counseling or direct referral to one of several driver improvement programs. Three versions of the DDC were evaluated as rehabilitation alternatives: the standard 8-hr classroom Driver Improvement Program (DIP); a programmed learning version of the DDC consisting of a tape-recorded lecture series and student workbook augmented by four hours of classroom instruction; and a second programmed learning course consisting of the same recorded materials and self-instruction workbook plus a 1-hr classroom meeting primarily for testing purposes. A no-treatment control group was included. The evaluation examined the impact of the exceptions made to predesignated treatment assignment and assessed the relative effectiveness of each course version. The impact of the exceptions was found to be minor. A few differences in group composition were found but multiple regression analytic techniques controlled for the potentially biasing effects of these variables. Modest but significant reductions in citation recidivism were detected for the DIP version of the course. It is recommended that the DDC be further explored and evaluated as a potentially valuable driver rehabilitation treatment.

OCCUPANT RESTRAINT LEGISLATION HANDBOOK: A GUIDE FOR PROPONENTS. FINAL REPORT

Intended as a working guide to individuals and organizations involved in efforts to gain legislative approval of general safety belt usage or child restraint laws, this handbook contains information and data to support arguments on behalf of occupant restraint legislation, and to overcome nonsupporter objections and reservations, and strategies, tactics, and methods for communicating the above data to state legislators, traffic safety officials, police officials, media representatives, and others. The focus of the manual is on developing effective state-level campaigns to obtain passage of occupant restraint laws. Appended are a document containing information needed by proponents to argue effectively the case for occupant restraint legislation (designed for distribution as an informational booklet), examples of safety belt usage legislation, and references to general information on safety belts, societal costs associated with motor vehicle accidents, attitudinal studies and surveys related to safety belt usage, research related to compulsory safety belt usage laws, constitutionality of safety belt usage laws, compulsory safety belt usage laws in foreign countries, and public information and education campaigns on safety belt usage.

MOTOR VEHICLE TRAFFIC FATALITIES IN THE UNITED STATES. TRENDS FROM 1975 TO 1978 AND 1979 4-MONTH ESTIMATES

The following U.S. motor vehicle traffic fatality data from 1975 to 1978 are tabulated and discussed: fatality rates according to registered vehicles, vehicle miles traveled, licenses issued, and population; fatalities by vehicle type and for pedestrians; fatalities by posted speed limit; state-by-state and regional comparisons of fatalities and rates; and fatalities by age groups. Traffic fatality estimates for the first four months of 1979 show an alarming increase over 1978 for the first three months (up 13.8%, 19.2%, and 12.4%, respectively) while Apr 1979 increased by only 2.2% over Apr 1978. Weather conditions and increased travel are considered to be the primary factors accounting for the large increases. Traffic fatalities in 1978 were 12.6% higher than in 1975 and are continuing to rise in 1979. The increase was primarily among occupants (or riders) of motorcycles (41% increase), light trucks, including pickups, vans, and four-wheel drive vehicles (37% increase), and heavy trucks (41% increase). Fatalities as a function of population have risen by about 10% over the 1975-1978 period, primarily due to increased vehicle use; other fatality rates have remained relatively constant. The increase of fatalities on high-speed highways has been substantial (25% over the 4-year period), while the increase on lower speed roads has been almost negligible. Reduced availability of gasoline is likely to reduce overall fatalities in 1979.

RESTRAINT SYSTEM/SPEED LIMIT PUBLIC INFORMATION MATERIALS CATALOG. NUMBER 1. SUPPLEMENT 1

The Restraint System/Speed Limit Public Information Materials Catalog is designed for use by persons developing public information programs on restraint systems and speed limits. Section 1 pertains to restraint systems. The first part contains a list of promotional materials which are listed alphabetically by organization name and arranged by type of material (movies, print ads, pamphlets, news releases, promotional gimmicks such as calendars, television and radio spots, posters, bumper stickers, television and radio scripts, editorials, audiotapes, slides). Three broad subject headings (child restraints, general restraint systems, passive restraints) are provided under which are listed the organizations which have produced pertinent materials. The second part lists articles and reports, arranged by title. Organization and author indexes are provided. Section 2, pertaining to speed limits, is similarly arranged. The subject headings for the promotional materials are accident/injury reduction, fuel/energy conservation, holiday driving, minority/youth, and police functions/laws. No indexes are provided for the articles and reports. Materials and reports may be borrowed free of charge for three weeks and may be renewed depending upon demand. Requests may be mailed or telephoned to the Univ. of Michigan, Hwy. Safety Res. Inst., Public Communication Proj.

ALCOHOL/SAFETY PUBLIC INFORMATION MATERIALS CATALOG. NUMBER 3. SUPPLEMENT 3

The Alcohol/Safety Public Information Materials Catalog is designed for use by persons developing public information programs on alcohol and highway safety. Part 1 contains a list of promotional materials which are listed alphabetically by organization name and arranged by type of material (pamphlets, posters, audiotapes, radio and television spots, news releases, bumper stickers, promotional gimmicks (e.g. matchbooks), print ads, bus cards/transit advertising, movies, radio and television scripts). Nine broad subject headings (alcoholism, the disease; alternatives to drunk driving; drugs other than alcohol; legal aspects; minority groups/youth; physiological impairment; general information; responsible drinking/know your limits; social drinking) are provided under which are listed the organizations which have produced pertinent materials. Part 2 lists articles and reports, arranged by title. Organization, author, and subject indexes are provided. Materials and reports may be borrowed free of charge for three weeks and may be renewed depending upon demand. Requests may be mailed or telephoned to the Univ. of Michigan, Hwy. Safety Res. Inst., Public Communication Proj.

CASE STUDY OF THE INNOVATION PROCESS CHARACTERIZING THE DEVELOPMENT OF THE THREE-WAY CATALYTIC CONVERTER SYSTEM. FINAL REPORT

The development of the three-way catalytic converter is traced from its origins in automaker and chemical firm research in the 1950's, to present plans preparing the system to be the auto exhaust emission control device most widely used on American cars in the 1980's. Among multiple forces leading to the decision by major automakers in the late 1970's to adopt the system were tightening exhaust emissions regulations; the development of low-cost, mass-producible system components; and institutional factors, including strong system advocates, internationalization of the auto industry, and the desire of certain technology-oriented automakers to defend their U.S. market shares by adoption of the system. It is concluded that the three-way catalytic (TWC) converter system may become the dominant emission control device for American-market cars in the 1980's if problems are resolved relating to adaptation of the system to 6- and 8-cylinder engines, reduction in requirements for precious metals, and the development of secure sources of supply for those metals. Appended are the auto pollution control device introduction schedule, illustrations of three major current TWC converter systems, tentative supply network for TWC systems, and tabulations of fuel economy and emissions for vehicles with advanced conventional engine systems, and of 50-state fuel economy figures for various manufacturers.

TIRE TREADWARE VALIDATION. VOL. 1: TECHNICAL REPORT. FINAL REPORT

A study initiated in July 1974, under Contract DOT-HS-4-00920 was continued to quantify the wear characteristics of six different passenger tire constructions: two radial, two bias, and two bias belted groups. Comparison road tests were conducted in three widely separate locations to determine possible effects of different pavement types on the treadwear relationships between the convoy road test method and the previous accelerated wear technique. The study confirmed the results of the earlier program, which concluded that accelerating tire treadwear rates by a significant factor does not distort the rank order of the treadwear comparison of those tires tested. It was concluded that the mechanism of tire wear is not a function of the rolling distance of the tire, but of the sliding distance of the tire tread elements in contact with the road; the free rolling resistance of these tires requires less energy than the distance the tire is required to slip. Road design and surfacing material can play a more significant role in tire wear than tire construction, compound, design or manufacturer. It was concluded that while a mil of rubber and the miles to which it relates is not a significant indicator of relative tread loss, the functional relationship of a unit of tread volume loss to the slip energy invested at the tire/road interface is significant.

FARS, FATAL ACCIDENT REPORTING SYSTEM, 1978 ANNUAL REPORT

The first of two volumes (the second containing supporting data) of the fourth annual FARS (Fatal Accident Reporting System) activity report contains statistical tables and graphs of data on fatal motor vehicle traffic accidents in the 50 states and the District of Columbia taken from the FARS file for the years 1976 through 1978 (99% complete as of 20 Apr 1979). The data are drawn from various sources from state to state, but generally include police accident reports, driver license files, motor vehicle registration files, vital statistics, and state highway department records. These sources are supplemented occasionally by emergency medical service reports and hospital records. A summary of 1978 statistics is followed by sections covering fatalities, state statistics, accidents (collision, environment), vehicles (passenger cars, motorcycles, pickups/vans, trucks, school buses), occupants (alcohol, restraints, age, convictions), and pedestrians/pedalcyclists. In 1978, there was a total of 50,226 people killed in the U.S. in 44,336 fatal accidents; fatalities per 100 million vehicle miles traveled increased between 1977 and 1978 by 0.9%; the number of vehicles and motorcycles in fatal accidents increased by 6% and 10%, respectively, over 1977.

DRIVER EDUCATION AND THE LICENSING OF 16 AND 17 YEAR OLDS

Regressional analyses were used to estimate the strength of the relationship among driver education enrollment, laws requiring driver education for licensing before age 18, and the rate of licensing of 16-and 17-year-olds in the U.S. Results show that driver education is significantly and positively related to the licensing rate of these youth, that this relationship is much weaker than that reported by Robertson and Zador (coefficient for regression of driver licensing on driver education was .80 vs. .25 for the present study), that the relationship was not greatly diminished when economic and mobility factors were controlled, that the relationship was considerably stronger between 1971 and 1975 (.42) than between 1965 and 1970, and that the presence of driver education laws had a significant negative relationship with licensing of young drivers and a significant positive relationship with driver education enrollment. These results suggest that driver education probably accounts for some increase in the licensing of young drivers.

INVESTIGATION OF MOTOR VEHICLE/BICYCLE COLLISION PARAMETERS, VOL. 1. FINAL REPORT

Seven hundred motor vehicle/bicycle accidents were investigated in-depth, data coded and stored, and analysis performed with the objective of determining countermeasures. Exposure measures were taken at each accident site during the same period of time under matching environmental circumstances. Univariate analysis of the data file was conducted to provide some insight into the principal factors of the accident population. The analysis established that the principal cause of these accident types was human error, with the bicyclist making the majority of the errors. The younger age groups of the bicyclists were statistically overrepresented; there was no significance associated with the sex of the cyclist or the motor vehicle driver. Conclusions are that improvement in bicycle safety depends on simultaneous activity in three areas: education, regulation, and enforcement. Of all risk-taking behavior, riding on the wrong side of the road by bicyclists is most clearly identifiable. Support by Federal and state governments for increased bicycle safety measures is urged, including educational programs. Bicycle visibility should be improved and the lightweight hand brake should be redesigned. Studies should be undertaken on feasibility of licensing bicyclists and bicycles, of using marked bikeways on urban streets and banning bicycles during certain specified hours. Design of the bicycle should be studied for injury-inducing potential, and that of the motor vehicle continuously monitored for possibly dangerous external changes.

ADVANCED MOTORCYCLE HANDLING AND DYNAMICS. VOL. 2, FINAL TECHNICAL REPORT

A study was conducted of the potential of unconventional motorcycle configurations for improved accident avoidance performance, including both front and rear steered motorcycles with low center of gravity and long wheelbase. Stability and obstacle avoidance characteristics were investigated analytically using mathematical models of both the uncontrolled and rider-controlled motorcycle. An analysis was also performed of the sensitivity of the optimum front-rear brake proportioning to road surface conditions and lateral acceleration. Although the rear steered configuration proved unacceptable from a control standpoint, the front steered configuration has advantages in the moderate-to-high speed regime in terms of the margin of safety in performing an obstacle avoidance maneuver, and rider skill level required in braking. These advantages accrue at the expense of low speed maneuverability and added weight, and of overall complexity of the machine; visibility and conspicuity are less satisfactory than in the conventional motorcycle. Further evaluation of safety factors and marketability is needed.

ADVANCED MOTORCYCLE HANDLING AND DYNAMICS. VOL. 3, APPENDIX A, DESCRIPTION OF COMPUTER PROGRAMS. FINAL REPORT

Information is provided for a series of computer programs based on a linear model with four motion degrees of freedom; lateral displacement, yaw, roll, and steer angle. Included are two programs (NORIDER and NORIDE2) which compute the eigenvalues and eigenvectors of the system of equations representing the uncontrolled motorcycle, a time simulation including a rider control model for an obstacle avoidance maneuver, and a program which computes the frequency response of a motorcycle to steer torque and rider body torque inputs. As all these programs require a description of the mass properties of the machine and rider, documentation has been included on a support program which computes the mass center and moments and products of inertia of any assemblage of masses. The geometry used for the motorcycle model underlying all the programs is illustrated and a nonmenclature list is provided.

NDT (NONDESTRUCTIVE TESTING)/ROAD CORRELATION. FINAL TECHNICAL REPORT

In the continuation of an evaluation of water-coupled ultrasonics to identify tire anomalies which lead to degraded tire performance, 75 recapped test tires were obtained, including bias, bias-belted, and radial, and were scheduled for 10,000 mi of highway durability testing. This test program was undertaken to supplement data generated during a previous contract, which involved a comparison of several nondestructive test (NDT) methods, and which determined that water-coupled ultrasonics produced the most accurate and repeatable data for three-dimensionally positioning tire anomalies. In the present study, the tires generally obtained only one-third the 10,000 mi durability due to catastrophic failures and treadwear anomalies. These tires were NDT-Inspected pre- and post-testing to analyze the ability of water-coupled ultrasonics to differentiate between those tire anomalies which lead to degraded road performance and those which do not. The results show that although water-coupled ultrasonics can determine anomalies, the effectiveness of the device depends on the experience of the data analyst. Application of water-coupled ultrasonics will be limited until a data base is established that enables anomalies to be appropriately identified.

AN ANALYSIS OF MOPEDS AS A POTENTIAL SAFETY PROBLEM IN THE UNITED STATES. VOL. 2: DATA ANALYSIS AND USAGE AND ACCIDENT PROJECTIONS. FINAL REPORT

An attempt was made to forecast the possible moped accident problem in the U.S. over the next five to ten years. The project was designed to formulate a procedure to forecast the nature and scope of the potential moped accident problem; to use the procedure to predict outcomes for input values such as sales volume, usage patterns, and crash rates; and based on the outputs, to recommend NHTSA (National Hwy. Traffic Safety Administration) research and safety program action. Results of an analysis of available data on U.S. moped sales, usage, and accident involvement are presented. After an introduction and overview of the project, some demographic information on U.S. moped riders is presented, and the typical use of the vehicle, based on various consumer surveys, is described. A descriptive analysis of moped accidents is presented, based on police-reported accident data provided by 11 states. The methods are described by which the available data were utilized to develop projections of the number of in-use mopeds and moped accidents, injuries, and fatalities through 1988. Project findings are discussed, and the following recommendations are proposed regarding future NHTSA-sponsored research: to encourage the collection of police- reported state accident data, to collect exposure data, to develop a decision analysis approach to moped safety problems, to develop and test accident countermeasures, to determine licensing requirements for moped operators, to develop licensing skill test procedures, to develop licensing knowledge test and accompanying manuals, and to develop moped helmet standards.

RESEARCH INPUT FOR COMPUTER SIMULATION OF AUTOMOBILE COLLISIONS. VOL. 2. STAGED COLLISIONS: TESTS NO. 1 THROUGH NO. 5. FINAL REPORT

Results are presented for the first five of 12 full-scale staged collisions, as well as an outline of test plans and procedures used to document the events. The staged collisions were designed to develop a library of experimental data which could be used to validate accident reconstruction techniques such as SMAC (Simulation Model of Autobile Collision) and CRASH (Calspan Reconstruction of Accident Speeds on the Highway). The test matrix focused on data gaps indentified in Phase 1 (Vol. 1) involving intermediate- and subcompact-size vehicles. Collision configurations included frontal, side, and rear impacts with both cars moving at velocities up to 40 mph. The vehicles measured parameters such as: vehicle compartment accelerations (X, Y, Z components); angular yaw velocity; compartment pitch, roll and yaw angle; wheel angular velocities; steer angle; and vehicle trajectory. Each collison was photographically covered with ten high-speed, 16 mm data cameras. Occupant injury criteria data were obtained on the driver and front seat passenger in the target vehicle according to Federal Motor Vehicle Safety Standard 208 requirements.

SMALL CAR DRIVER INFLATABLE RESTRAINT SYSTEM EVALUATION. VOL. 3: INVESTIGATION OF POTENTIAL CRASH SURVIVABILITY OF A CURRENT PRODUCTION SUBCOMPACT VEHICLE EQUIPPED WITH AN ADVANCED DRIVER RESTRAINT SYSTEM. FINAL REPORT.

A Chevette body buck modified to accept the Minicars Res. Safety Vehicle (RSV) advanced driver restraint system was used in a series of sled tests to establish the potential benefits to be derived from installing the advanced RSV system in a current production subcompact vehicle. Tests conducted earlier using the existing Chevette driver station geometry and a modified version of the General Motors Air Cushion Restraint System (ACRS) established 30-mph barrier equivalent velocity (BEV) frontal impact protection. Results indicate that in the absence of problems created by severe upper firewall intrusion, passive driver frontal impact protection can be provided with the Minicars system to 40-mph BEV. The necessary modification of the existing driver station geometry would entail redesigning and reorienting the column assembly, providing a more involved steering assembly link-up to the steering gear box, rearranging the instrument panel, and reconfiguring the driver side lower dash to provide a knee restraint. Recommendations include complete integration of the system into the Chevette, with a detailed estimate of its associated costs; conducting a sufficient number of vehicle crash tests to define system performance in all statistically significant crash modes; and using RSV accident analysis methodology to calculate from the above the expected cost-effectiveness of the system if installed on all new vehicles in its class. Data traces for sled tests are appended.

SMALL CAR DRIVER INFLATABLE RESTRAINT SYSTEM EVALUATION. VOL. 4. EVOLVING A LOW MOUNT PASSENGER AIR CUSHION RESTRAINT SYSTEM (ACRS) FOR THE VEGA SUBCOMPACT VEHICLE. FINAL REPORT

A low mount air cushion restraint system (ACRS) was investigated to determine if such a system could be designed for the Vega subcompact vehicle to protect normally seated front occupants in 30-mph barrier equivalent velocity (BEV) frontal impacts. An ACRS was developed by conducting sled tests in which passenger size and position effects were also investigated. Sled test results indicate the evolved system would satisfactorily protect a wide range of normally seated occupant sizes in 30-mph impacts, although the Vega compartment deceleration signature at this condition is atypically severe; providing such a restraint would probably require extensive modification of the right side of the dashboard. A right front passenger restraint system should be designed to accommodate the 50th percentile male and 5th percentile female size occupants. The system should be further refined to protect child passengers in the proximity of the dashboard (out of position). An identical system in a subcompact vehicle with a more reasonable compartment deceleration characteristic at 30-mph BEV could require less propellant; a reduced inflator charge would have beneficial effects on the injury measures recorded during out-of-position tests. Data traces of the tests are appended.

FIELD TEST EVALUATION OF REAR LIGHTING DECELERATION SIGNALS: 1. ANALYTICAL AND EXPERIMENTAL STUDIES. INTERIM REPORT

Analytical and experimental studies related to braking signals which indicate deceleration level were conducted in order to select a limited set of such signaling concepts for field evaluation of their effectiveness in reducing rear-end crashes. Literature reviews of prior simulator, driving, and field tests, as well as accident data analyses, indicated that braking deceleration signals would have limited applicability, but one field test produced a large reduction in rear-end crashes. Potential means of coding rear lighting deceleration signals were developed, and were subjectively evaluated in day and night driving. A study of flash rates showed that not more than three rates could be discriminated between 1 Hz and 9 Hz, with an automotive bulb. Based on the foregoing tests, a driving test was used to evaluate brake signaling displays, including deceleration signals and a simulated brake signal failure. Measures related to car-following and rear-end collision performance were clearly degraded by the brake signal failure, and there were a few differences between the conventional and experimental configurations. Measurement of the braking deceleration distributions used by taxis and motor pool vehicles showed that taxis are a suitable fleet for field testing braking deceleration signals, based on over 30,000 mi. of exposure in both groups. Five configurations of braking signals are recommended for evaluation in a field test of their effects on rear-end crashes.

MATERIAL APPLICATIONS IN FUTURE AUTOMOTIVE STRUCTURE. VOL. 2: FINAL REPORT

Candidate materials which might be used in future automotive structures were evaluated in terms of general materials properties, availability, manufacturability, cost and their effects on crashworthiness, durability, and nondamageability. Body on frame, unibody, and unibody van vehicle structures were analyzed using finite-element analysis and mass-spring modeling to determine limits and boundaries of materials application. It is concluded that low carbon steel will remain the primary candidate material based on current cost projections, with the use of high strength low alloy (HSLA) steel replacing it in some applications. Vehicle first cost in dollars will increase with the use of the candidate materials. Raw materials are available to permit the extensive application of aluminum alloys, HSLA steels, plastic, and glass/or carbon fiber-reinforced composites in future automotive structures. Mill capacity will continue to remain marginal, on a supply-demand basis, vehicle durability and crashworthiness comparable to that with low carbon steel are achievable with the alternate materials at a weight reduction. Front and rear end nondamageability can be improved with alternate materials, especially elastomeric plastics, without weight penalty. Aluminum alloys and glass-reinforced composites will continue to compete for hang-on components, the former material being more expensive but offering greater weight reduction. Plastics applications, as elastomerics, will increase for front and rear end nondamageable energy management up to 15 mph to 20 mph. New process developments such as reaction injection molding will increase plastics potential in exterior body panels for weight reduction and cost effectiveness. New material developments in laminate or composite forms such as metal skin thermoplastic laminate and mixed fiber hybrid composites provide potential weight reductions at lower cost penalties, when combined with a steel space frame design.

LONG LIFE HYDRAULIC BRAKE SYSTEM. FINAL TECHNICAL REPORT

An analytical and experimental program was conducted to design a long-life brake system for passenger vehicles which would double the length of intervals between servicing of conventional systems. The design approach was constrained to be compatible with existing vehicle configurations and not to differ radically in braking principle. Formal study objectives were to analyze the state of the art of hydraulic brake systems in order to identify system assembly and/or component design requirements which will assure a significant increase in service life without maintenance and repairs, and without affecting safety, performance, or fuel economy; to develop techniques which can be utilized objectively in quantifying system durability; and to recommend procedures suitable for use in compliance testing. Service life was initially found to be defined by friction pair maintenance in the 30,000 mi. to 40,000 mi. range. Subsequent servicing requirements were necessitated by a number of inhibiting mechanisms derived in large part from fluid degradation, metal corrosion, and rubber deterioration. A long-life design approach was specified, satisfying a doubled friction pair lifetime and a 100,000 mi. balance of system service-free life. Component-by-component design approach alternatives are given, and three test procedures described for evaluating compliance with the postulated standard. Benefit-cost analysis demonstrated that the benefits of reduced accidents and consumer maintenance outweigh the costs.

HIGHWAY TRAFFIC SAFETY MANAGEMENT ORIENTATION MODULE DEVELOPMENT. ADMINISTRATIVE EVALUATION. FINAL TECHNICAL REPORT

The tasks are outlined in developing a workbook and cassette tape module for a self-instruction orientation course on Administrative Evaluation of Highway Safety Programs to be added to a set of seven modules prepared in 1976 and 1978 on various highway safety management subjects. The modules are distributed for use by new personnel hired by State Highway Safety Offices and by other employees requiring refresher training in specific aspects of the Highway Safety Program. This latest module represents the current policies and procedures for administrative evaluation of highway safety projects at National Hwy. Traffic Safety Administration and state agencies.

CALIBRATION AND TEST PROCEDURES FOR THREE YEAR OLD CHILD DUMMY. FINAL REPORT

Four three-year-old-child dummies, SA 103C models, were tested at the Univ. of Michigan's Hwy. Safety Res. Inst. (HSRI) and the National Hwy. Traffic Safety Administration Engineering Test Facility at TRC (Transportation Res. Center) of Ohio in order to determine the ranges of responses of the test dummies in specified calibration testing and to diminish or eliminate the variability of responses obtained in earlier tests at the two facilities. The dummy head accelerator mounting was revised to reduce ringing, and the rib cage structure attachment modified to eliminate bottoming. A revised loading fixture was designed to facilitate the lumbar spine calibration. The modified dummies produced consistent calibration response data within the proposed limits of Docket 78-09 at both (HSRI and TRC) labs. Several procedures are recommended for reducing the level of dependency on technique in dummy calibration. The impact point on the chest should be remeasured and remarked on the chest skin before each impact to obtain consistent response data. An improved suspension system for the impact piston should be investigated which would provide better trajectory control. Consideration should be given to a slightly spherical rather than planar face on the impact piston to reduce the effects of off-center impacts due to the irregularities of the molded dummy skin.

ESTABLISHMENT OF THE REPEATABILITY OF PERFORMANCE OF THE SA103C THREE-YEAR OLD CHILD TEST DUMMIES. FINAL REPORT

Four SA103C three-year-old-child dummies were first tested in a series of static and dynamic component tests in accordance with test procedures specified in the proposed standard 49 CFR, Part 572, Subpart C. A series of 60 whole dummy performance tests was then conducted on an HYGE accelerator sled with each dummy tested in a sequence of six replicate runs in two different child restraint seats (GM Love Seat and Chrysler Mopar Safety Seat). At sled impact velocities of 30 mph and 20 mph, the following primary measures of dummy sled test performance were analyzed statistically: peak head resultant acceleration, peak chest resultant acceleration, maximum head center of gravity horizontal displacement, and maximum knee horizontal displacement. Analysis of the absolute deviations of each data point from the overall means demonstrated that the dummy variations were within an acceptable level for all performance measures. Performance comparison overlay time history graphs are presented for direct comparisons. Analysis of variance of sled test data, and sample calculations of the statistical analyses are appended.

NDR [NATIONAL DRIVER REGISTER] RAPID RESPONSE SYSTEM SUPPORT SERVICE. FINAL REPORT

It is recommended that the National Driver Register Rapid Response System (NDR3S) be implemented using a public packet switched network because of its high availability (99%), very short meantime to repair (seconds), simplicity of operation, and moderate costs. This approach provides the Federal government the greatest flexibility during the initial stages of system implementation and growth. A continuing task of the NDR staff should be that of monitoring the performance, composition, and cost of the system. When the design has been stabilized and the terminal population is adequate, a government-operated system might be implemented. It is planned to operate a demonstration system during FY 1981 consisting of three rapid response states and one remote batch only state. Following evaluation of this demonstration system, the system will be expanded at the rate of three rapid response states per year through FY 1984 and four per year thereafter. Remote batch only states will be added at the rate of one year to a (presently known) total of seven. Results are presented of an analysis of the manner in which computer systems operated by state driver register systems can be connected to the NDR3S computer operating at the Transportation Computer Center in Washington, D.C. An implementation plan is presented, depicting the sequencing and dependencies of about 60 major events during the NDR3S system life. Cooperative agreements that must be executed by the Federal government and participating states are presented. Also provided is a privacy and security plan for the NDR3S.

SUBCOMPACT VEHICLE ENERGY ABSORBING STEERING COLUMN EVALUATION AND IMPROVEMENT. EXECUTIVE SUMMARY. FINAL REPORT

Testing was undertaken to analyze the interrelationships between and the effects of automobile interior surfaces on driver injury in frontal impacts of subcompact vehicles. At velocities near 20 mph, variations in steering wheels, steering columns, and knee restraints did not substantially affect the driver's injury severity as described by Federal Motor Vehicle Safety Standard 208. At velocities near 25 mph, effects of these variations became evident. Steering wheels which deform easily in a mode which aligns the steering wheel rim and hub to the driver's torso resulted in significant reductions in the driver's chest injury severity. The tube and mandrel type steering column, designed to reduce binding due to bending forces, produced less chest injury. The passive knee restraint substantially increased driver femur forces. With no knee restraint, the driver submarined under the steering wheel and instrument panel; with the knee restraint, the forward translation of the driver's knees was restricted, causing the driver to rotate about the H-point into the steering wheel and windshield. This reduced head and chest injury, but contributed to neck hyperextension.

SUBCOMPACT VEHICLE ENERGY ABSORBING STEERING COLUMN EVALUATION AND IMPROVEMENT. VOL. 1: ANALYSIS OF ACCIDENT DATA, ENGINEER'S POINT OF VIEW. INTERIM REPORT

Automobile accident cases were analyzed statistically in an effort to determine the injury-causing factors involved in subcompact vehicle driver/steering wheel assembly interaction during impact. Principal component, contingency table, and discriminant function analyses were applied to data sets consisting of 108 MDAI (multidisciplinary accident investigation) team cases and 53 cases recorded by the Univ. of Birmingham (England) Accident Res. Unit. Frontal impacts involving unrestrained drivers were analyzed. The analysis developed a methodology for the determination and illustration of injury-causing and injury-indicating factors in automobile accidents. For the MDAI file, it was found that injury was strongly related to steering wheel rim damage, and exhibited a highly probable interaction with floor deformation. For the Birmingham file, injury exhibited a significant interaction with steering wheel spoke damage, and a highly probable interaction with the case vehicle damage energy. For the MDAI file, injury exhibited a substantial relationship with the total change in case vehicle velocity, was strongly related to whether the direction of principal force was nearest zero degrees or 30 degrees, and showed a highly probable interaction with occupant height. For the Birmingham file, injury was strongly related to total change in velocity and occupancy age. A contingency table analysis of the combined files standardized for their statistical differences indicated that the Vega (almost exlusively in MDAI file) steering column energy-absorbing device is most effective in cases of minimal deformation, while the Capri (exclusively in Birmingham file) column is most effective in cases of severe deformation.

SUBCOMPACT VEHICLE ENERGY ABSORBING STEERING COLUMN EVALUATION AND IMPROVEMENT. VOL. 3: APPENDICES. INTERIM REPORT

Automobile accident cases were analyzed statistically in an effort to determine the injury-causing factors involved in subcompact vehicle driver/steering assembly interaction during impact. Principal component, contingency table, and discriminant function analyses were applied to data sets consisting of 108 MDAI (multidisciplinary accident investigation) team cases and 53 cases recorded by the Univ. of Birmingham (England) Accident Res. Unit. Frontal impacts involving unrestrained drivers were analyzed. These appendices contain the following information: coding and distribution of significant variables; sample collision performance and injury report used for MDAI data; sample accident investigation report, Univ. of Birmingham; MDAI data codebook; Birmingham data codebook; listing of accident cases and important variables for the MDAI 108, MDAI 78, and Birmingham 53 data files; example of a CRASH (Calspan Reconstruction of Accident Speeds on the Highway) 2 computer simulation; and frequency distributions and classifications for important MDAI and Birmingham variables. Appended is a discussion of the measurement of thoracic injury in collision simulations using anthropomorphic dummies.

DEVELOPMENT OF AERODYNAMIC DISTURBANCE TEST PROCEDURES. VOL. 2: TECHNICAL REPORT. FINAL REPORT

Research was conducted using the first full-scale crosswind disturbance test facility in the U.S., a facility developed for the National Hwy. Traffic Safety Administration which is capable of providing a 35 mph crosswind for a nominal 120 ft test length. The crosswind responses of 20 different vehicle models (8 conventional cars (plus 4 trailers), 2 station wagons, 3 light trucks (one with camper), 3 vans, and 4 two-wheelers (including a moped and a bicycle)) were surveyed, and complete instrumented vehicle tests were conducted on 5 of these vehicles (Honda Accord, Chevrolet Station Wagon (alone and with a 17-ft trailer), Ford Econoline E300 Van, VW Microbus, and Ford F-250 pickup/Pilgrim cabover camper). Three test procedures (steering fixed, steering free, and driver control of lane position) were used in three different cross wind disturbance configurations (straight pulse, doublet pulse, and a shaped profile). Results show that passenger cars, station wagons, trucks, and most vans have virtually no crosswind sensitivity problems; potential problems were found for the VW Microbus, and the pickup/camper (in winds higher than 35 mph), cars pulling trailers, and mopeds. Key vehicle parameters dictating this yaw response sensitivity are the distance between the aerodynamic and tire force centers, tire restoring moment (including understeer gradient), and the basic aerodynamic side forces. A simple analytical relationship in these terms was developed to predict steady-state yaw rate in steady winds. Collected results led to recommendations for the most useful test procedures, performance measures, crosswind configurations, and definitions of the relationship between subjective driver ratings and objective measures. This last step represents the first attempt at defining maximum allowable limits of vehicle crosswind sensitivity.

REVIEW OF LEGAL LITERATURE PUBLISHED BETWEEN JULY, 1974 AND JULY, 1978 PERTAINING TO ALCOHOL AND DRUG INVOLVEMENT IN HIGHWAY SAFETY

This annotated review of the legal and law-related literature published between Jul 1974 and Jul 1978 on the subject of alcohol and other drug involvement in highway crashes includes articles published in American and foreign English language journals and periodicals, as well as nine books. The first part of the review, covering journals and periodicals, is divided into the following categories: legal issues arising under anti-drunk driving laws, special sanctions under such laws, tort liability and drunk driving, field studies on the relationship between anti-drunk driving laws and highway safety, and law in foreign jurisdictions. The second part reviews the nine books. Appended are British and Canadian statutes appropriate to the subject.

CRITERIA FOR IMPLEMENTATION OF OPTIMUM INTEGRATION ALGORITHM INTO THE WRECKER PROGRAM. VOL. 2: FINAL TECHNICAL REPORT [VEHICLE STRUCTURAL DYNAMICS]

Three research versions of the WRECKER program, a computer simulation program to analyze the response of vehicle structures under crash loading, were created by incorporating new integration methods in the WRECKER I and II programs. The integration algorithms are the variable time step Newmark, the EPISODE (Efficient Program for Integrating Stiff Ordinary Differential Equations), and the FU (explicit, variable step, fourth order procedure for systems of second order ordinary differential equations, allowing for a user-specified artificial damping term) methods. These research versions were tested with seven illustrative problems (eight node cantilever plate, cantilever beam with slave nodes, elastic plastic spring, S-frame without strain rate, frame with inclined roller support, fixed end beam with discontinuity device (hinge), and clamped cylindrical panel (tang)). Results show that the new methods are superior to the implicit method used in WRECKER II and more accurate and stable than the explicit method used in WRECKER I. Appended are descriptions of test cases, computer program input and output modifications, descriptions of programs (including listings), and a state-of-the-art report.

TRI-LEVEL STUDY OF THE CAUSES OF TRAFFIC ACCIDENTS. VOL. 1: CASUAL FACTOR TABULATIONS AND ASSESSMENTS. FINAL REPORT

Causal result tabulations and related analyses are presented from Phases 2 through 5 of a tri-level (3 levels of detail) study of traffic accident causation. Police reports and other baseline data on the Monroe County, Indiana study area were collected on the first level. On the second level, teams of technicians responded to 2258 accidents at the time of their occurrence to conduct on-scene investigations. Concurrently, 420 of these accidents were examined independently by a multidisciplinary team on the third level. Other special surveys were also conducted. One or more human factors were cited by the in-depth team as probable causes in 92.6% of the accidents. Environmental factors were cited as probable causes in 33.8% of the accidents, while vehicular factors were identified as probable causes in 12.6%. The major human direct causes were improper lookout, excessive speed, inattention, improper evasive action, and internal distraction. Leading environmental causes were view obstructions and slick roads. Major vehicular causes were brake failure, inadequate tire tread depth, side-to-side brake imbalance, tire underinflation, and vehicle-related vision obstructions. Vision (especially poor dynamic visual acuity) and personality (especially poor personal and social adjustment) were found related to accident involvement. Knowledge of the driving task was not found to be related. Information is presented in the following sections: introduction; methodology overview; causal result tabulations; trend analysis of causal results; analysis of accident severity as a function of accident causation; driver conditions and states in combination with other factors; analysis of assessment practices; second and third level comparisons; representativeness of study samples and area; and summary, conclusions, and recommendations.

TRI-LEVEL STUDY OF THE CAUSES OF TRAFFIC ACCIDENTS. VOL. 2: SPECIAL ANALYSES. FINAL REPORT

In conjunction with a tri-level study of traffic accident causation, several special analyses were conducted concerning human, vehicular, and environmental factors in relation to accident involvement and causation. Persons involved in traffic accidents in the Monroe County, Indiana study area were compared with a control group of drivers not involved in investigated accidents. Separate examinations were made of driver vision, driver knowledge, driver psychological and personality factors, and driver characteristics and culpability in relation to accident involvement and causation. Vision (especially poor dynamic visual acuity) and personality (especially poor personal and social adjustment) were found related to accident involvement. Knowledge of the driving task was not found to be related. It was found that culpable drivers (male and female) had significantly less road/area familiarity than did nonculpable drivers. Separate analyses employing cluster analytic and Automatic Interaction Detector procedures were made to obtain a better understanding of human, vehicular, and environmental characteristics in relation to accident causation. Major human direct causes were determined to be improper lookout, excessive speed, inattention, improper evasive action, and internal distraction. Leading environmental causes were view obstructions and slick roads. Major vehicular causes were brake failure, inadequate tire tread depth, side-to-side brake imbalance, tire underinflation, and vehicle-related vision obstructions. Other analyses involved motorcycle accidents and causes: assessment of the differences between characteristics of accidents involving motorcycles and those involving other vehicle types, comparison of tri-level study motorcycle data with 1973 Indiana State Police data, and analysis of the tri-level data in terms of accident causation. The importance of other drivers failing to see motorcyclists and the need for motorcyclists to keep headlights on, wear highly visible clothing, and decrease speed at intersections were underscored.

TRI-LEVEL STUDY: MODIFICATION, TASK 3. A VALIDITY ASSESSMENT OF POLICE-REPORTED ACCIDENT DATA. FINAL REPORT

Under a modification to the "Tri-Level Study of the Causes of Traffic Accidents," a special analysis was conducted to assess the validity of police-reported traffic accident data. Information theory and signal detection theory techniques were used to assess police data reliability by comparison with multidisciplinary accident investigation and technical level data collected during the tri-level study. Results indicate that the accident level variables reported by the police with least reliability were vertical road character, accident severity, and road surface composition. The most reliably reported data were those concerned with the accident location, date, and number of drivers, passengers, and vehicles. The informativeness of the police reports with respect to driver/vehicle characteristics was practically nil, with the exception of driver age, sex, and vehicle model (for which the police were correct most of the time). It was also found that police reports provided very little information regarding the presence of different human conditions and states, vehicle defects, and environmental/road deficiencies. The sensitivity of police investigators to all accident causes was low, when causes were categorized into human direct, human indirect (conditions and states), and environmental; police were more reliable in reporting human direct causes than vehicle, environment, and human indirect causes (least reliable). In the assessment of alcohol presence and involvement, a strong and significant difference existed between male and female drivers, with a lower reliability associated with females.

TRI-LEVEL STUDY: MODIFICATION, TASK 1. FINAL REPORT ON POTENTIAL BENEFITS OF VARIOUS IMPROVEMENTS IN VEHICLE SYSTEMS IN PREVENTING ACCIDENTS OR REDUCING THEIR SEVERITY

Under a modification to the "Tri-Level Study of the Causes of Traffic Accidents," a separate analysis was conducted to assess the potential accident prevention and severity reduction benefits of various possible improvements in vehicle systems. Based on a review of the literature and in consultation with the National Hwy. Traffic Safety Administration, the following potential improvements were defined for assessment: vehicle life time brake components; pad/lining wear indicator; underinflation warning device; improved wet traction tires; improved maneuverability and control; standardization of driver controls; standardization, reduction, or modification of blind zones; light failure warning device; improved brake lights; cross-polarized lights and windshields; improved forward lighting; and rapid windshield defrost system. Benefits were assessed by four members of the Inst. for Res. in Public Safety's engineering staff who manually reviewed 420 individual in-depth case reports to extract additional information and to assess hypothetically the benefits derived from equipping one or more of the vehicles in each accident with each of these systems. "Possible" benefits recorded for the various systems ranged from a low of 0.5% (two accidents) for standardization of driver controls; to a high of 8.8% (37 accidents) for improved brake lights. The maximum "certain" benefit (8 accidents) was for vehicle lifetime brake components, which were also judged to be of "possible" benefit in up to 5.5% of these accidents (23).

TRI-LEVEL STUDY: MODIFICATION, TASK 2. FINAL REPORT ON DRIVER/VEHICLE CHARACTERISTICS RELATED TO VEHICLE CONDITION AND CAUSATION AND AN ASSESSMENT OF INDIANA PMVI [PERIODIC MOTOR VEHICLE INSPECTION] EFFECTIVENESS TO REDUCE THE FREQUENCY AND SEVERITY OF ACCIDENTS CAUSED BY VEHICULAR-RELATED MALFUNCTIONS/ DEGRADATIONS

Under a modification to the "Tri-Level Study of the Causes of Traffic Accidents," a separate study was performed to investigate the relationships between driver/vehicle characteristics and vehicle condition and accident causation. An investigation was also conducted to evaluate the effectiveness of Indiana periodic motor vehicle inspection (PMVI) in improving overall vehicle condition, and in inspecting and repairing components which were judged to have caused or increased the severity of accidents. It was found that vehicles in the poorest condition were driven by accident victims less than 20 years old, those without a high school degree, divorcees, laborers, individuals whose annual family income is less than $3000, or victims who had not taken a driver education course. Accident- involved vehicles in the poorest condition were domestic vehicles 12 years or older. Vehicles in the best overall condition were driven by accident victims aged 55 to 64, those with postgraduate or professional degrees, married persons, students, white collar workers, professionals, persons with family incomes of $15,000 or more, or those who had taken a driver education course. Accident-involved vehicles in the best overall condition were foreign and less than one year old. Vehicles implicated in accidents most frequently were old (12 years or more), more often convertibles, vans, or pickup trucks, and were driven by persons less than 20 years old. Concerning PMVI effectiveness, 51.7% of the components judged to be causally implicated in accidents were either not mandatorily inspected through Indiana PMVI, or, if inspected, were later judged to be in a failing condition at the time of inspection. Of all components checked which were defective at the time of the accident, 28.9% were judged to be defective at the time of the state inspection.

TRI-LEVEL STUDY: MODIFICATION, TASK 4. FINAL REPORT ON THE RELATIONSHIPS BETWEEN DRIVER CHARACTERISTICS AND ACCIDENT CAUSATION

Under a modification to the "Tri-Level Study of the Causes of Traffic Accidents," a separate analysis was conducted to determine whether driver characteristics were related to factors which were judged to cause or increase the severity of accidents. The following "causes" were considered: inattention, internal or external distraction, improper lookout, misjudgment of distance, false assumption, improper maneuver or driving technique, driving technique inadequately defensive, excessive speed, inadequate signal, improper evasive action, performance errors, alcohol impairment, mental/emotion, experience/exposure, slick roads, highway-related, ambience-related, and vehicular. Statistical tests were employed to evaluate causation differences on the basis of driver trip plan, fatigue, number of passengers, age, driving experience, vehicle familiarity, and road area familiarity. Results indicate driver fatigue, trip plan, road area familiarity, number of passengers, and age were related to factors which cause accidents. For males, vehicle familiarity and for females, driving experience were also related.

TRI-LEVEL STUDY: MODIFICATION, TASK 5. AN EXAMINATION OF DRIVER CHARACTERISTICS AND COLLISION PRODUCING ERRORS OF ACCIDENT AND TRAFFIC VIOLATION REPEATERS. FINAL REPORT

Under a modification to the "Tri-Level Study of the Causes of Traffic Accidents," a separate analysis was conducted to examine the characteristics and collision-producting errors of accident- and traffic violation-prone drivers. Statistical tests were employed to evaluate the differences between accident/conviction repeaters and nonrepeaters. Results indicate that accident repeaters, when compared to nonrepeaters, were more frequently young (aged 20 to 24), male, single, had attended but did not graduate from college, and caused accidents more frequently because of decision errors (specifically, improper evasive actions). Drivers with prior convictions, when compared to those with no prior convictions, were more frequently between the ages of 20 and 24, male, single, indicated that they had attended but not completed college, were white-collar workers (less frequently professionals or housewives), and caused more accidents more frequently because of excessive speed or alcohol impairment. It was found that the accident and conviction repeaters were more frequently exposed to accident risk, a factor which could account for the other effects found. The accident and conviction nonrepeaters were found to cause the accident investigated just as often as the repeaters.

TRI-LEVEL STUDY: MODIFICATION, TASK 6. A FINAL REPORT ON SUPPLEMENTAL CAUSATION ASSESSMENTS THROUGH HYPOTHESIS TESTING

Under a modification to the "Tri-Level Study of the Causes of Traffic Accidents," a separate analysis was conducted to assess statistically the potential causal involvement of selected vehicle factors. Accident situations in which the presence of component defects were considered to be a potential danger (vehicle control, bald tires on wet curves, brake defects and rear-end collisions, inoperable turn signals in intersection accidents while turning) were identified, and the condition of vehicles in these situations compared to that of vehicles in accidents where the component defect was considered to be of less importance. The following vehicle defects were considered: defective front or rear tread, underinflated front or rear tires, mixed tire types, inoperable turn indicators, steering freeplay, loose suspension, and brake imbalances and inefficiencies. Control variables (human, environmental, and vehicle design factors) which might themselves account for the differences found were identified, and statistical methods used to control for their effects. Results indicate that driver/vehicle combinations involved in control-loss accidents were associated with the presence of a combination of human, vehicle, and environmental factors, where poor vehicle condition was a contributing factor. Driver/vehicle combinations involved in accidents on wet curves were also associated with the presence of a combination of human, vehicle, and environmental factors, where underinflated front tires were a contributing factor.

TRI-LEVEL STUDY OF THE CAUSES OF TRAFFIC ACCIDENTS. EXECUTIVE SUMMARY. FINAL REPORT

Traffic accident causation was investigated by collecting and analyzing data on three levels: police reports and other baseline data for the Monroe County, Indiana, study area were collected; teams of technicians responded to accidents at the time of their occurrence to conduct on-scene investigations (a total of 2258 investigations); concurrently, 420 of these accidents were examined independently by a multidisciplinary team. General population surveys were also conducted. Human factors were cited by the in-depth team as the probable causes in 92.6% of the accidents investigated. Environmental factors were cited as probable causes in 33.8% of these accidents, while vehicular factors were identified as probable causes in 12.6%. The major human direct causes were improper lookout, excessive speed, inattention, improper evasive action, and internal distraction. Leading environmental causes were view obstructions and slick roads. The major vehicular causes were brake failure, inadequate tread depth, side-to-side brake inbalance, underinflation, and vehicle-related vision obstructions. Vision (especially poor dynamic visual acuity) and personality (especially poor personal and social adjustment) were found related to accident involvement. Knowledge of the driving task was not shown to be related. Other findings were derived related to the following areas: cluster and automatic interaction detector analyses of accident data, motorcycle accident analysis, driver characteristics as they relate to vehicle condition and causation, reliability of police-reported accident data, and representativeness of study data.

NEW AND REBUILT BRAKE MASTER CYLINDER SURVEY AND PERFORMANCE EVALUATION. FINAL REPORT

A market survey was conducted to determine the production volume of the various automotive brake master cylinder rebuilders and the most popular models currently in use. A purchase plan for 274 rebuilt master cylinders, based on this information, was formulated. The plan also included 126 units from original equipment manufactures (OEM) and after- market manufacturers. The 400 units were tested in accordance with SAE J1153 test procedure. Test results were analyzed for compliance with the performance requirements of SAE J1154 and applicable manufacturers' specifications. Performance categories were established and used to make comparisons among the OEM, aftermarket, and rebuilt groups as well as the various manufacturers' groups. A post-test inspection was conducted in an effort to determine failure causes. The high number of unit failures which occurred during testing appeared to indicate that certain test conditions are too severe. Piston seal damage was prevalent in many master cylinder failures. Some correlation was found between the high-temperature durability test and failures due to seal damage. The OEM units, as a group, demonstrated the lowest failure rate, followed by after-market and rebuilt units. Cylinder bore measurements taken after testing indicated that some of the rebuilders may be removing excessive amounts of metal during bore reconditioning.

ACCIDENT CAUSATION METHODOLOGY DEVELOPMENT FOR THE NATIONAL ACCIDENT SAMPLING SYSTEM. FINAL REPORT

Research was undertaken as one of several steps in the development of an overall analysis system for a National Accident Sampling System (NASS) currently being implemented to provide nationally-representative data on traffic accidents. Issues are explored related to the design of statistical methods to estimate the determinants of traffic accidents using NASS data. Criteria are recommended for selecting precrash variables for use in analysis. Relevant exposure measures, decision rules for their definition, and data sources are identified. A method is discussed for estimating multidimensional contingency tables from supplementary margins of varying detail and drawn from different samples which "represent" the same population. Analysis procedures are demonstrated for handling some of the peculiar problems of traffic accident data analysis and rate computation. Results of a field trial of preliminary methodology design are reported, along with recommendations for further development. A basic design for a causation methodology appropriate to NASS is recommended.

MULTIDISCIPLINARY HIGHWAY COLLISION INVESTIGATION TRAINING COURSE. FINAL REPORT

Three two-week courses to train accident investigators and allied specialists were planned, conducted, and evaluated. Each course was conducted once during Nov 1978, Mar 1979, and May 1979 in Phoenix, Ariz., using the syllabus entitled "Multidisciplinary Highway Collision Investigation Training," developed to fulfill the training requirements of state and local teams to bring them into compliance with Highway Safety Program Standard 18. The course and training program were constructed to provide the following: full consideration and integration of specific and special areas of accident studies advocated by the National Hwy. Traffic Safety Administration; the necessary training for a State Highway Safety Program, for accident investigation and reporting; real-world, on-scene accident experience to students, using experienced instructors; formal instruction by acknowledged experts and international authorities in investigative techniques, human, vehicle, and environmental factors, new techniques, and methodology; student involvement with facilities that are devoted to automotive safety, engineering research, development, and testing, with emphasis on the crash environment; and evaluation of student assessments of course content and quality of instruction.

NATIONAL DRIVER REGISTER (NDR) ALTERNATIVE PROGRAM COST EVALUATION. FINAL REPORT

Results are presented of a comparative cost analysis of operational and functional concepts for the operation of three distinct National Driver Register (NDR) systems. The primary objective was to determine the costs that would accrue to the participating states and to the Federal government for operating a National Driver Register Rapid Response System (NDR-RRS) as specified in Sections 220 through 231 of the House version of the Surface Transporation Assistance Act of 1978 (HR 11733). For comparison, costs were projected for continuation of the present voluntary Batch/Mail NDR system and for a proposed voluntary RRS that NDR has been designing to augment present capabilities. It was determined that the incremental cost impact for the 1984-1990 life cycle (stated in 1979 dollars) to implement the HR 11733 system is $19,084,000 (265%) greater than the existing Federal costs and $396,931,900 (5475%) more than existing state costs. The incremental cost impact to implement HR 11733 is $11,261,600 (158%) greater than the cost to implement the proposed voluntary RRS on the Federal level and $386,062.00 (2215%) greater for the states.

NATIONAL SYMPOSIUM ON COMMERCIAL TRUCK EXPOSURE ESTIMATION. VOL. 2: PROCEEDINGS. FINAL REPORT

A compilation is provided of papers presented at a symposium on commerical truck exposure estimation which was held on 9-11 Apr 1979 in Wasington, D.C. under the sponsorship of the Dept. of Transportation. The symposium agenda, questions posed and answers provided at the various sessions, and a list of attendees are included. The general areas covered by the 22 formal presentations include: background (what is exposure data, why is it needed, what does it look like), general needs (at the national level, for accident analysis), measures of truck exposures, techinques for exposure estimation, vehicular obervation techniques, and uses of exposure data.

EVALUATION OF A NONCONTACT DISPLACEMENT GAGE FOR MEASUREMENT OF ANTHROPOMORPHIC DUMMY CHEST DEFLECTION. FINAL REPORT

An eddy-current, noncontacting displacement gauge for monitoring Part 572 anthropomorphic dummy chest deflections during vehicle crashes, which was developed under contract DOT-HS-7-01550, underwent evaluation at the National Hwy. Traffic Safety Administration's Safety Res. Lab., Riverdale, Md. The test series was preceded by a static calibration of the dummy/gauge configuration. The instrumented dummy was subjected to a series of high- and low-level pendulum drop tests simulating Federal Motor Vehicle Safety Standard 208. A sled test series was utilized to compare seat belt loading and corresponding chest deflection for simulated 30 mph barrier impacts. No configurational, functional, or application problems were identified during testing. Because the chest deflections observed in the sled/belt configuration were very small, it is recommended that the system undergo sled testing using a steering wheel and column and allowing the dummy to impact the wheel.

DEVELOPMENT OF AN EDDY CURRENT NONCONTACT DISPLACEMENT GAGE FOR MONITORING ANTHROPOMORPHIC DUMMY CHEST DEFLECTIONS. FINAL REPORT

An eddy-current, noncontacting displacement gauge has been developed for monitoring Part 572 anthropomorphic dummy chest deflections during vehicle crashes. The gauge is configured to be bolted to the Part 572 dummy with no modification. The guage is designed to accommodate 3 in of chest deflection, and includes oscillator and demodulator electronics within the gauge head. Linearization of the gauge's output signal as a function of dummy chest deflection is achieved by a look-up table applied to the digitized signal. Detailed calibration of the gauge/dummy configuration has verified the overall system linearity. Kaman noncontacting displacement transducer specifications are appended.

CORRELATION OF BRAKING SYSTEM DEFECTS AND PERFORMANCE INSPECTION. VOL. 2: TECHNICAL REPORT. FINAL REPORT

The design was reviewed of a low-cost torsion bar brake dynamometer prototype developed by AVCO under Contract DOT-HS-5-01188, to suggest changes in the design, to construct two prototypes, and to conduct tests for evaluating the prototypes against three commercially available brake testers. The original design was modified to reduce the number of power transmission components and to provide a firmer basis for the torsion bar design. Two prototypes were constructed and tested, along with three commercially available testers: a low-speed roller (Hormann), a high-speed roller with inertia capability (Sun), and a platform tester (Bear). Evaluation criteria included accuracy, repeatability, ability to detect known defects, and cost. The prototype is ranked highest using the criteria, followed by the low-speed roller; the high-speed roller and the platform tester are classified as unacceptable. It is recommended that the long-term durability of the prototype be determined by placing it in service at a periodic motor vehicle inspection facility.

URBAN CROSSING PROBLEMS. FINAL REPORT

In a study designed to collect data on pedestrian accident causal factors based on observation of pedestrians and pedestrian-vehicle interaction behaviors, observation data were collected using a Closed Circuit Television (CCTV) system from 36 urban intersections in two U.S. cities. Data from 6,300 street-crossing observations were analyzed to attempt further specification of certain infrequently occurring accident patterns identified in previous research, and to identify new patterns or potential accident causal types (PACTS). Fourteen PACTS were initially hypothesized, eight considered sufficiently important to recommend their further investigation; the requirements for subsequent research are specified, including a right-of-way challenge; pedestrian overreliance on a friendship group, or on other pedestrians in the crosswalk; pedestrian preoccupation or distraction by conversation; and pedestrian slow crossing. Low priority PACTS include the pedestrian caught by signal change and the driver going through crosswalk stop. Frequently occurring individual potential errors and error combinations are discussed. The CCTV system is described and evaluated. Data tables supporting the study design are appended, as well as the procedure for sampling within an intersection, descriptions of study data base variables, lists of potential errors and predisposing factors, and safe street crossing guidelines.

NATIONAL DRIVER REGISTER (NDR) ALTERNATIVE PROGRAM COST EVALUATION. PT. 2. FINAL REPORT

Results are presented of an analysis of costs that would accrue to both the Federal government and the states, specifically and in aggregate, to meet the operational requirements for each of three alternative National Driver Register (NDR) design concepts. The three system concepts are entitled Problem Driver Pointer System, Phased-in All Driver Pointer System, and All Driver Pointer System. Also presented are summary findings from the Pt. 2 study to permit gross comparisons with the HR 11733 proposal and the current Batch/Mail System. The alternative "pointer" systems are ones in which data items maintained by the NDR consist only of driver identifiers (plus the state identification) and all records of violations and related actions are stored by the states. The HR 11733 and Batch/Mail Systems are "index" systems wherein certain substantive driver record data (revocation date, reason for revocation, etc.) are stored at the NDR. It is recommended that the Problem Driver Pointer System be chosen for implementation to improve the NDR. This recommendation is based on analyses indicating that this system is the least costly, provides the most useful information, is the most acceptable type of system to the states, and will stimulate state participation.

IMPACT OF FMVSS 208 COMFORT AND CONVENIENCE ON VEHICLE MANUFACTURING. FINAL REPORT

A major deterrent in the public acceptance of existing motor vehicle passive and active safety restraint systems, is the lack of comfort and convenience in their use. The purpose of Federal Motor Vehicle Safety Standard (FMVSS) 208, Comfort and Convenience, is to correct this deficiency by specifying standards governing belt fit, belt pressure tension, use of rear occupant emergency locking retractors, warning systems, belt guides and stand-offs, and latch plate accessibility. The domestic 1979 Model Year passenger and light truck and van fleets were analyzed for compliance. The results indicated that the 1979 fleets are generally in non-compliance in the areas of chest location and belt pressure for torso belt fit; availability of emergency locking retractors for rear seats; free standing belt guides for rear seats; and audible and indicator light warning systems for belt non-engagement. The design changes required to correct these deficiencies are relatively minor and can be instituted within the 1981 Model Year time frame. Results of an analysis of the impact on manufacturing lead time and per unit costs for rulemaking compliance are given by manufacturer and vehicle model. Appendices include the survey evaluation procedure, a sample data sheet, vehicle models and seat options, and the cost methodology.

DESIGNING A HEALTH/LEGAL SYSTEM: A MANUAL. FINAL REPORT (DRUNK DRIVING CASES)

A manual is presented for use by state, county, and local organizations in improving their case disposition process for persons arrested for drunk driving. This process combines the public health system, which attempts to prevent and treat the underlying drinking problem, and the traffic law system, which uses punishment and the threat of punishment to deter drinking/driving. System-level information is presented on case disposition aspects of health/legal systems and on interaction of case disposition elements (e.g. courts and probation departments) with other elements (e.g. treatment agencies). Information sources are indicated for more detailed design of specific components of the disposition process (e.g. presentence investigation). General principles of health/legal systems are described, and detailed descriptions and assessments of generic types of systems now operating are presented (reduced charge, probation, reduced sentence, and administrative). Methods are outlined for developing an analytic description of a jurisdiction's health/legal system as a design tool. A three-step method for designing systems improvements is described and illustrated with examples drawn from the experience of current health/legal systems. An introduction to program evaluation as applied to health/legal systems is provided as well as an extensive bibliography. Appended are a description of the approach used to collect descriptive data about operating health/legal systems, some findings derived from the data, and summary descriptions of ten representative systems which were visited and observed; also appended are forms for use in developing a system description, and a list of the alcohol program coordination agency in each state.

DATA ANALYSIS OF TRACTOR-TRAILER DRIVERS TO ASSESS DRIVERS' PERCEPTION OF HEAVY DUTY TRUCK RIDE QUALITY. FINAL REPORT

Questionnaires were distributed to members of the International Brotherhood of Teamsters (IBT) and the Professional Drivers Council (PROD) to obtain attitudinal information from these drivers of heavy-duty tractor trailers concerning ride quality and safety and to assess the interrelationships among driver biographical, health, and truck profiles as they affect comfort, safety, and ride quality. Over 36% of the IBT drivers (3608 of whom responded) and 52% of the PROD drivers (299 of whom responded) stated that they experienced "problems which cause major discomfort during normal operations or problems which make it almost impossible to drive the truck." Tractor make was found to have an important impact on ride comfort, two makes being outstanding in terms of comfort and driver preference. Other factors having an important effect on ride comfort are tire type, fifth wheel type, rear suspension, trailer configuration, shocks, seat adjustments, and trailer type. Strong linear relationships were found between riding comfort and the following health and vibrational variables: state of health, experience of fatigue, relationship of health problems to driver comfort, awareness of vibration, kind of vibration observed, and vibration awareness with truck loaded or empty. Driver weight, height, or sex; single vs. sleeper operations; and driving in the East vs. the West were not found to be importantly related to driver comfort. Middle-aged drivers appeared to be more dissatisfied with ride quality than were younger or older drivers. Owners of trucks reported more satisfaction with ride quality than did drivers of company trucks.

THE YAW STABILITY OF TRACTOR-SEMITRAILERS DURING CORNERING. FINAL REPORT

The yaw stability of tractor-semitrailers in steering-only maneuvers is examined by means of computer simulation and full-scale tests. The tests were conducted on as-designed vehicles as well as vehicles modified with frame and front suspension stiffening elements. Results show that while tractor yaw instability can occur well below the rollover threshold for certain vehicles, modified stiffness parameters can eliminate such premature yaw instability. Computerized simulation study of the influence of design and operating variables on tractor yaw stability served to classify the relative importance of different suspension stiffness options, as well as tire mix, fifth wheel placement, and trailer loading practices. Results show that remarkably low levels of tractor yaw stability are possible with certain combinations of design and in-use variables. A set of measurements of tractor-semitrailer ride vibrations is also reported as an add-on task.

DEVELOPMENT AND TESTING OF TECHNIQUES FOR INCREASING THE CONSPICUITY OF MOTORCYCLES AND MOTORCYCLE DRIVERS. FINAL REPORT

An investigation was made to determine whether the incidence of multi-vehicle motorcycle crashes might be reduced by improving the conspicuity of the motorcycle-driver unit. An analysis of Hwy. Safety Res. Inst. data files (a sample of about 10,000 motorcycle crashes in Texas in 1975, and a like-sized sample of car accidents for the same state and period), and a review of several other published analyses of motorcycle accidents clearly showed the overinvolvement of motorcycles (relative to cars and trucks) in accidents in which the other vehicle is executing a maneuver (generally a left turn) across their path. More than 30 conspicuity treatments were developed and demonstrated for subjective appraisal. A sample of countermeasures was evaluated in the field by means of a gap-acceptance procedure in which traffic conditions were normal and car drivers were unaware of their study participation. Results indicate that daytime conspicuity can most effectively be improved by use of fluorescent garments or steady or modulating lights. Nighttime conspicuity seems to be aided by use of retroreflective garments and running lights. All items found to produce significant conspicuity effects were found to be cost-beneficial. Limited tests with mopeds indicated that automobile drivers' responses were much different from their responses to motorcycles. Results suggested that the use of a fluorescent flag would be beneficial for mopeds.

THE NATIONAL PARTS RETURN PROGRAM. VOL. 1: INDEPENDENT REPAIR FACILITIES. FINAL REPORT

Recruitment requirements, enrollment techniques, and membership characteristics are described for independent repair facilities involved in the National Parts Return Program (PRP), which solicits the voluntary submittal of failed automotive components and information by independent auto repair shops, new car dealers, high-mileage fleets, and automotive parts suppliers. Program members submit actual failed parts or failure information to the National Hwy. Traffic Safety Administration via Kappa Systems, Inc. (KSI). The three major operational functions of KSI in this program are described: data collection, data management (i.e. parts and information processing, failure analysis, updating manual and automated files, producing monthly reports), and production of the PRP Newsletter. Data are analyzed which were submitted by the PRP membership during the contract year covering 1 Jul 1978 through 30 Jun 1979, as well as for CY 1976-CY 1978. Results are discussed in terms of three related parameters measuring program effectiveness: quantity of part or information inputs; percentage of enrollees that were "active," or activity level; and number of inputs per active shop ratio, or activity rate. The review initially centers on contributions received from the total membership, and then focuses on regional activity levels and rates of independent repair shops. Actual parts returned continued to decrease, but information inputs rose markedly during the past contract year. Repair shop regional activity level decreased from CY 1976 to CY 1978 but increased in CY 1979; activity rates decreased over the entire four-year period. Recommendations to improve PRP effectiveness during CY 1980 include: to gather more information about new members, to initiate a two-state enrollment campaign, and to enhance the incentive program.

FINANCING OPTIONS FOR DIAGNOSTIC INSPECTION PROGRAMS. FINAL REPORT

Innovative methods are described to be used as a substitute for a specific funding mechanism by a state or local government planner or private entrepreneur to obtain funds from currently available sources in order to initiate a motor vehicle diagnostic inspection program. Public and private financing are addressed to correspond with the two basic administrative organizational approaches to the various inspection concepts. State and local government funding mechanisms include Federal domestic assistance and state- and locally-generated revenues. A description of these mechanisms is followed by that of the spectrum of funding mechanisms, including commercial banks and capital investment firms, applicable to private, for-profit and nonprofit enterprises such as cooperatives and auto service clubs. A set of matrices are presented which show for the public and private sectors the funding options that are appropriate for each of the diagnostic inspection program concepts. It is indicated that although no single funding mechanism is best suited for a particular inspection concept, with the exception of the Cooperative Bank, it is possible to tailor several funding mechanisms to fit a given inspection program concept. A glossary of financial terms is appended.

NATIONAL MAXIMUM SPEED LIMIT AND HIGHWAY SAFETY PROGRAM REGIONAL WORKSHOPS. FINAL REPORT

Four regional workshops were conducted, addressing the National Maximum Speed Limit (NMSL) and highway safety programs. The attendees included the chief administrators and field commanders of state law enforcement agencies. The workshops accomplished four major objectives: to keep law enforcement administrators abreast of federal programs impacting on police traffic services, including the 55 NMSL, and to review the National Hwy. Traffic Safety Administration's (NHTSA) programs and research activities; to enable state law enforcement administrators to identify for NHTSA key problem areas in the delivery of police traffic services in order to provide direction for future NHTSA research efforts; to review the Highway Safety Act of 1978 and attendant Federal regulations as they impact on police traffic services, including the NMSL; and to provide a forum for the participants for the exchange of ideas, mutual support, and regional planning for improvement in the delivery of police traffic services. Recommendations covered various aspects of State/Federal relationships, highway safety programs, and combined efforts for NMSL enforcement. The following findings were among those most frequently mentioned at the workshops. Highway safety programs other than the 55 mph NMSL enforcement suffer because of the Federal emphasis on the NMSL. Various methods are being considered for energy conservation, including fixed post (usually 15 minutes per hour), reducing administrative use of vehicles, two-man patrol cars, etc. Average speeds are still above 55 mph. Because of budgetary reductions, highway safety programs and/or personnel have been cut, leading to enforcement problems on secondary roadways. One solution might be to coordinate activities with the sheriff's department. Both stationary and moving radar have increasingly been employed in speed enforcement efforts. Not all states are receiving legislative support at the state level for their 55 NMSL enforcement efforts. Specific reports on the four workshops are appended.

NATIONAL MAXIMUM SPEED LIMIT (NMSL) ENFORCEMENT PRACTICES AND PROCEDURES, PHASE 2. INTERIM REPORT

Various National Maximum Speed Limit (NMSL) patrol configurations (combinations of police personnel, equipment and assigned responsibilities) were evaluated to determine their relative productivity (NMSL violators contacted per manhour expended on NMSL enforcement), cost effectiveness (net revenue from NMSL violators fined per NMSL violator contacted) and effect on NMSL compliance on selected highways in six states (selected for geographical distribution and with state law enforcement agencies among which all of the selected enforcement configurations would be employed under controlled conditions). Objectives were to determine if productivity rises as the visibility of the patrol unit is decreased (marked patrol car to unmarked patrol car or aircraft); if productivity rises as the number and sophistication of speed measuring devices are increased (speedometer only, stopwatch, moving radar, stopwatch and moving radar); and the effects of these variables on NMSL compliance. It was found that decreasing patrol unit visibility increased productivity, as did increasing the number and sophistication of speed detection devices. Four apprehending officers working with one officer in an unmarked stationary radar equipped detecting unit is the most cost effective NMSL enforcement configuration evaluated in terms of potential net income per contact. The single officer unmarked car unit equipped with a moving radar in addition to the speedometer has the highest productivity of all patrol configurations evaluated. Lowering visibility and increasing the availability of speed detecting devices increased apprehension of passenger car violators equipped with CB radios but not of commercial driver violators. A statistically significant relationship between enforcement operations and NMSL compliance was not shown in the data collected. Extensive data are provided in tables and charts; evaluation plans and details are appended.

ADMINISTRATOR'S GUIDE TO SPEED ENFORCEMENT/PATROL CONFIGURATIONS FOR THE NATIONAL MAXIMUM SPEED LIMIT (NMSL). FINAL REPORT

Information is provided for law enforcement administrators and other decision makers on the various enforcement practices and procedures utilized by states' law enforcement agencies to enforce the 55 mph national maximum speed limit (NMSL). During Phase 1 of this project, 43 state law enforcement agencies completed and returned a resource document which provided information concerning their NMSL enforcement practices and resources, and site visits were conducted in ten states to observe NMSL enforcement operations. During Phase 2, the cost effectiveness and benefits of various enforcement configurations were evaluated with the cooperation of the following six state agencies: Arizona Dept. of Public Safety, Colorado State Patrol, Iowa Dept. of Public Safety, Maryland State Police, Massachusetts Dept. of Public Safety, and Ohio State Hwy. Patrol. Evaluated were patrol configurations (single unit up to 5-unit); marked and unmarked patrol cars, and aircraft; and speedometers, moving and stationary radars, and stopwatches. Recommendations include reducing the visibility of vehicles used in NMSL enforcement, and increasing the availability of moving radar and stopwatches to officers for detecting and measuring violator speeds.

RESTRAINT USAGE AND EFFECTIVENESS ON THE NATIONAL CRASH SEVERITY STUDY

National Crash Severity Study (NCSS) and Opinion Res. Corp. (ORC) data collection methods are examined as they relate to the differences in the rates of restraint usage reported by the two sources. It is found that if a similar portion of the NCSS file is considered (drivers of 1964 through 1978 model year passenger cars in urban areas) and is then adjusted to the distribution of model years observed by ORC, the estimate of usage for NCSS is 13.8% vs. 14.1% for ORC. This does not support the widely-held view that the accident-involved population differs significantly from the overall driving population in seat belt usage rates. An examination of the entire NCSS file indicates that certain groups apparently have higher usage rates: females, people over 24 years old, those in smaller or newer cars, those involved in urban accidents, and those who have suffered less severe injuries. Restraint effectiveness estimates based on NCSS data show that the lap and shoulder restraint system occupants suffered over 60% fewer serious injuries than did unrestrained occupants, and that lap-belted occupants had over 40% fewer serious injuries than unrestrained occupants. Over 50% and over 20% fewer fatalities were found, respectively, for lap/shoulder-restrained and lap-belted occupants vs. unrestrained occupants. It is concluded that NCSS data seem generally consistent with ORC data, and with those from the Fatal Accident Reporting System, and the Restraint System Evaluation Program, for estimates of restraint usage and effectiveness. NCSS data provide greater detail, particularly for occupants suffering serious trauma.

REMARKS AT 55 MPH NATIONAL MAXIMUM SPEED LIMIT CONFERENCE, REGION 3, BALTIMORE HILTON HOTEL, BALTIMORE, MARYLAND, TUESDAY, MAY 22, 1979

The National Hwy. Traffic Safety Administration's (NHTSA) role in increasing voluntary compliance with the 55 mph national speed limit is addressed. The Surface Transportation Assistance Act requires the states to submit annually to the Secretary of Transportation data on the percentage of motor vehicles exceeding 55 mph for the 12-month period ending 30 Sep. The graduated compliance standards require no less than 30% compliance by the end of FY 1979, to no less than 70% compliance by the end of FY 1983 and for each year thereafter. The law requires total vehicle monitoring with Federal-aid highway funding dependent on compliance. Federal funding has been authorized for state 55 mph enforcement programs and for incentive grants to states exceeding the mandated criteria by more than 10%. NHTSA is assisting states in improving their 55 mph compliance programs and in increasing public support. In 1978, NHTSA conducted regional workshops in Washington D.C., Atlanta, Kansas City, and San Francisco to assist state officials involved in 55 mph public education programs. A model plan for managing 55 mph public communication programs has been provided to states. The Dept. of Transportation is developing a new national public service advertising campaign on 55. NHTSA is focusing its media efforts on operation C.A.R.E. (Combined Accident Reduction Effort), a cooperative campaign of state law enforcement agencies working together to enforce the 55 mph speed limit and other safety laws on major interstate routes during Memorial Day, July 4th, and Labor Day weekends. NHTSA is contacting businesses, associations, and public interest groups in an effort to develop grass-roots support for 55. NHTSA's basic strategy for promoting voluntary compliance involves cooperative efforts between business and community health and safety organizations.

EMERGENCY MEDICAL SERVICES INSTRUCTOR TRAINING COURSE

This four-unit course for training emergency medical services instructors consists of a sound/slide presentation and a student workbook. The presentation may be viewed by a group or individually. The four units include preparing to teach the EMT (emergency medical technician) course; developing EMT knowledge and skills; using training aids; and evaluating EMT knowledge and skills. A synopsis of each unit is presented, followed by statements to be completed during the presentation, and an application section containing questions to test knowledge after the presentation. Correct answers to questions and statements are provided in the back of the workbook. While having competence in the subject matter is vitally important, to be effective the instructor must be totally familiar with the structure of the course and competent in aiding each student to reach the course objectives. This instructor training course was developed to help the instructor attain these objectives and to prepare him to teach emergency medical care more effectively.

FEASIBILITY OF DEVELOPING TRAINING PROGRAMS DESIGNED TO IMPROVE DEFICIENT DRIVER FACTORS. VOL. 1: A REVIEW OF EXISTING DATA BASES AND RECOMMENDATIONS FOR FUTURE DATA COLLECTION. FINAL REPORT
HS-804 746

FEASIBILITY OF DEVELOPING TRAINING PROGRAMS DESIGNED TO IMPROVE DEFICIENT DRIVER FACTORS. VOL. 2: IDENTIFYING ACCIDENT AVOIDANCE BEHAVIORS: A GUIDE FOR ACCIDENT INVESTIGATORS. FINAL REPORT
HS-804 747

NATIONAL DRIVER REGISTER (NDR) ALTERNATIVE PROGRAM COST EVALUATION. FINAL REPORT
HS-805 120

NATIONAL DRIVER REGISTER (NDR) ALTERNATIVE PROGRAM COST EVALUATION. PT. 2. FINAL REPORT
HS-805 129

NDR [NATIONAL DRIVER REGISTER] RAPID RESPONSE SYSTEM SUPPORT SERVICE. FINAL REPORT
HS-805 072

PRINCE GEORGE'S COUNTY: A LOCAL HEALTH DEPARTMENT CONFRONTS THE YOUNG DRINKING DRIVER
HS-027 613

SMALL CAR DRIVER INFLATABLE RESTRAINT SYSTEM EVALUATION. VOL. 3: INVESTIGATION OF POTENTIAL CRASH SURVIVABILITY OF A CURRENT PRODUCTION SUBCOMPACT VEHICLE EQUIPPED WITH AN ADVANCED DRIVER RESTRAINT SYSTEM. FINAL REPORT.
HS-805 054

SMALL CAR DRIVER INFLATABLE RESTRAINT SYSTEM EVALUATION. VOL. 4. EVOLVING A LOW MOUNT PASSENGER AIR CUSHION RESTRAINT SYSTEM (ACRS) FOR THE VEGA SUBCOMPACT VEHICLE. FINAL REPORT
HS-805 055

THE ADDICTED DRIVER: A PROBLEM OF LAW OR MEDICINE?
HS-027 604

THE EFFECTS OF ALCOHOL ON THE DRIVER'S DECISION-MAKING BEHAVIOR. VOL. 2: APPENDICES. FINAL REPORT
HS-803 609

THERE IS MORE TO A DWI (DRIVING WHILE INTOXICATED) CASE THAN A BAC (BLOOD ALCOHOL CONCENTRATION) READING: A JUDGE'S RESPONSIBILITY TO THE DRINKING DRIVER
HS-027 605

TRI-LEVEL STUDY: MODIFICATION, TASK 4. FINAL REPORT ON THE RELATIONSHIPS BETWEEN DRIVER CHARACTERISTICS AND ACCIDENT CAUSATION
HS-805 096

TRI-LEVEL STUDY: MODIFICATION, TASK 5. AN EXAMINATION OF DRIVER CHARACTERISTICS AND COLLISION PRODUCING ERRORS OF ACCIDENT AND TRAFFIC VIOLATION REPEATERS. FINAL REPORT
HS-805 097

DRIVERS

DATA ANALYSIS OF TRACTOR-TRAILER DRIVERS TO ASSESS DRIVERS' PERCEPTION OF HEAVY DUTY TRUCK RIDE QUALITY. FINAL REPORT
HS-805 139

DEVELOPMENT AND TESTING OF TECHNIQUES FOR INCREASING THE CONSPICUITY OF MOTORCYCLES AND MOTORCYCLE DRIVERS. FINAL REPORT
HS-805 143

LATENT STRUCTURE MODELS APPLIED TO THE JOINT DISTRIBUTION OF DRIVERS' INJURIES IN ROAD ACCIDENTS
HS-026 399

PROJECT ADAPTS (ALCOHOL - DRIVERS AND PEOPLE - TEACHING SAFETY)
HS-027 614

REHABILITATION EFFECTIVENESS FOR SAFE PROJECT DRIVERS RECEIVING DEFENSIVE DRIVING COURSE TRAINING. A SUPPLEMENTAL EVALUATION REPORT. FINAL REPORT
HS-804 777

TECHNIQUES FOR PREDICTING HIGH-RISK DRIVERS FOR ALCOHOL COUN- TERMEASURES. VOL. 2. USER MANUAL. FINAL REPORT
HS-804 733

DRIVETRAIN

STUDY AND TEST TO CONFIRM AUTOMOBILE DRIVETRAIN COMPONENTS TO IMPROVE FUEL ECONOMY. VOL. 2. THE DRIVETRAIN DESIGN PROCESS WITH AN AUTOMATIC TRANSMISSION. INTERIM REPORT
HS-803 856

DRIVING

AN HONEST IMPLIED CONSENT LAW (DRIVING WHILE INTOXICATED OFFENSES)
HS-027 607

CHARACTERISTICS OF DWI'S (DRIVING WHILE INTOXICATED), ALCOHOLICS, AND CONTROLS
HS-027 598

DESIGNING A HEALTH/LEGAL SYSTEM: A MANUAL. FINAL REPORT (DRUNK DRIVING CASES)
HS-805 138

DRUNK DRIVING AMONG YOUTH AND YOUNG ADULTS. A DESCRIPTION OF A PILOT STUDY FOR REDUCING DRINKING AND DRIVING AMONG YOUNG PEOPLE IN RICHMOND, VIRGINIA
HS-027 616

EFFECTS OF ALCOHOL AND DIAZEPAM, SINGLY AND IN COMBINATION, ON SOME DRIVING PERFORMANCES
HS-027 611

IMPLEMENTATION OF A LARGE SCALE REHABILITATION PROGRAM EVALUATION (DRUNK DRIVING OFFENDERS)
HS-027 601

R.I.D.E. (REDUCE IMPAIRED DRIVING IN ETOBICOKE): A PREVENTION PROGRAMME FOR DRINKING DRIVING
HS-027 610

REHABILITATION EFFECTIVENESS FOR SAFE PROJECT DRIVERS RECEIVING DEFENSIVE DRIVING COURSE TRAINING. A SUPPLEMENTAL EVALUATION REPORT. FINAL REPORT
HS-804 777

THE CLASS THAT WAS DESIGNED TO TEACH - EACH ONE (DRINKING/DRIVING COUNTERMEASURE PROGRAM FOR ILLITERATE PERSONS)
HS-027 617

THE VISUAL DETECTION OF DRIVING WHILE INTOXICATED
HS-027 609

THERE IS MORE TO A DWI (DRIVING WHILE INTOXICATED) CASE THAN A BAC (BLOOD ALCOHOL CONCENTRATION) READING: A JUDGE'S RESPONSIBILITY TO THE DRINKING DRIVER
HS-027 605

DRUG

REVIEW OF LEGAL LITERATURE PUBLISHED BETWEEN JULY, 1974 AND JULY, 1978 PERTAINING TO ALCOHOL AND DRUG INVOLVEMENT IN HIGHWAY SAFETY
HS-805 082

THE NEW YORK STATE ALCOHOL AND DRUG REHABILITATION PROGRAM
HS-027 620

DRUNK

DESIGNING A HEALTH/LEGAL SYSTEM: A MANUAL. FINAL REPORT (DRUNK DRIVING CASES)
HS-805 138

DRUNK DRIVING AMONG YOUTH AND YOUNG ADULTS. A DESCRIPTION OF A PILOT STUDY FOR REDUCING DRINKING AND DRIVING AMONG YOUNG PEOPLE IN RICHMOND, VIRGINIA
HS-027 616

IMPLEMENTATION OF A LARGE SCALE REHABILITATION PROGRAM EVALUATION (DRUNK DRIVING OFFENDERS)
HS-027 601

DUMMIES

DEVELOPMENT OF TESTING AND EVALUATION OF CHILD RESTRAINT SYSTEMS AND CHILD TEST DUMMIES BY NHTSA (NATIONAL HIGHWAY TRAFFIC SAFETY ADMINISTRATION)
HS-027 536

ESTABLISHMENT OF THE REPEATABILITY OF PERFORMANCE OF THE SA103C THREE-YEAR OLD CHILD TEST DUMMIES. FINAL REPORT
HS-805 071

DUMMY

A COMPARISON BETWEEN PART 572 DUMMY AND HUMAN SUBJECT IN THE PROBLEM OF SUBMARINING
HS-027 544

CALIBRATION AND TEST PROCEDURES FOR THREE YEAR OLD CHILD DUMMY. FINAL REPORT
HS-805 070

COMPARISON OF PASSENGER INJURIES IN FRONTAL CAR COLLISIONS WITH DUMMY LOADINGS IN EQUIVALENT SIMULATIONS
HS-027 528

DEVELOPMENT OF AN EDDY CURRENT NONCONTACT DISPLACEMENT GAGE FOR MONITORING ANTHROPOMORPHIC DUMMY CHEST DEFLECTIONS. FINAL REPORT
HS-805 124

EVALUATION OF A NONCONTACT DISPLACEMENT GAGE FOR MEASUREMENT OF ANTHROPOMORPHIC DUMMY CHEST DEFLECTION. FINAL REPORT
HS-805 123

MODIFICATION OF PART 572 DUMMY FOR LATERAL IMPACT ACCORDING TO BIOMECHANICAL DATA
HS-027 549

DUTY

DATA ANALYSIS OF TRACTOR-TRAILER DRIVERS TO ASSESS DRIVERS' PERCEPTION OF HEAVY DUTY TRUCK RIDE QUALITY. FINAL REPORT
HS-805 139

DWI

CHARACTERISTICS OF DWI'S (DRIVING WHILE INTOXICATED), ALCOHOLICS, AND CONTROLS
HS-027 598

THERE IS MORE TO A DWI (DRIVING WHILE INTOXICATED) CASE THAN A BAC (BLOOD ALCOHOL CONCENTRATION) READING: A JUDGE'S RESPONSIBILITY TO THE DRINKING DRIVER
HS-027 605

DYNAMICS

ADVANCED MOTORCYCLE HANDLING AND DYNAMICS. VOL. 2, FINAL TECHNICAL REPORT
HS-804 911

ADVANCED MOTORCYCLE HANDLING AND DYNAMICS. VOL. 3, APPENDIX A, DESCRIPTION OF COMPUTER PROGRAMS. FINAL REPORT
HS-804 913

CRITERIA FOR IMPLEMENTATION OF OPTIMUM INTEGRATION ALGORITHM INTO THE WRECKER PROGRAM. VOL. 1: SUMMARY FINAL REPORT [VEHICLE STRUCTURAL DYNAMICS]
HS-805 083

CRITERIA FOR IMPLEMENTATION OF OPTIMUM INTEGRATION ALGORITHM INTO THE WRECKER PROGRAM. VOL. 2: FINAL TECHNICAL REPORT [VEHICLE STRUCTURAL DYNAMICS]
HS-805 084

DYNAMICS OF WHEELED RECREATIONAL VEHICLES
HS-026 402

EASE

TUNE UP YOUR BIKE FOR RIDING EASE AND SAFETY
HS-026 425

EASY

EASY RIDER--HARD FACTS: MOTORCYCLE HELMET LAWS
HS-026 394

ECONOMIC

CORPORATE STRATEGIES OF THE AUTOMOTIVE MANUFACTURERS. VOL. 3: PANORAMA OF SELECTED ECONOMIC AND OPERATING INFORMATION. FINAL REPORT
HS-804 587

ECONOMY

MANUFACTURER'S POLICIES CONCERNING AVERAGE FUEL ECONOMY STANDARDS. FINAL REPORT
HS-803 720

STUDY AND TEST TO CONFIRM AUTOMOBILE DRIVETRAIN COMPONENTS TO IMPROVE FUEL ECONOMY. VOL. 2. THE DRIVETRAIN DESIGN PROCESS WITH AN AUTOMATIC TRANSMISSION. INTERIM REPORT
HS-803 856

EDDY

DEVELOPMENT OF AN EDDY CURRENT NONCONTACT DISPLACEMENT GAGE FOR MONITORING ANTHROPOMORPHIC DUMMY CHEST DEFLECTIONS. FINAL REPORT
HS-805 124

EDUCATION

DRIVER EDUCATION AND THE LICENSING OF 16 AND 17 YEAR OLDS
HS-804 834

EFFECTIVENESS

DRIVER-VEHICLE EFFECTIVENESS MODEL. VOL. 1: FINAL REPORT
HS-804 337

DRIVER-VEHICLE EFFECTIVENESS MODEL. VOL. 2: APPENDICES. FINAL REPORT
HS-804 338

REHABILITATION EFFECTIVENESS FOR SAFE PROJECT DRIVERS RECEIVING DEFENSIVE DRIVING COURSE TRAINING. A SUPPLEMENTAL EVALUATION REPORT. FINAL REPORT
HS-804 777

RESTRAINT USAGE AND EFFECTIVENESS ON THE NATIONAL CRASH SEVERITY STUDY
HS-805 151

SEAT DESIGN--A SIGNIFICANT FACTOR FOR SAFETY BELT EFFECTIVENESS
HS-027 523

THE DELPHI PROJECT ON THE VIEW OF CRIMINAL JUSTICE OFFICIALS ON ALCOHOL SAFETY ADJUDICATION AND REFERRAL COUNTERMEASURE EFFECTIVENESS
HS-027 606

ELECTRIC

BATTERY POWERED ELECTRIC VEHICLES. STATE-OF-THE-ART 1978
HS-026 415

ELECTRO

DRIVER VISIBILITY QUALITY: AN ELECTRO-OPTICAL METER FOR IN-VEHICLE MEASUREMENT OF MODULATION TRANSFER (MTF). FINAL REPORT
HS-804 105

ELEMENT

JUDICIAL INTERVENTION: THE MISSING ELEMENT (ALCOHOLISM PREVENTION AND REHABILITATION)
HS-027 603

EMERGENCY

EMERGENCY MEDICAL SERVICES INSTRUCTOR TRAINING COURSE
HS-900 031

EMISSIONS

EVALUATION OF MOTOR VEHICLE EMISSIONS INSPECTION AND MAINTENANCE PROGRAMS IN OHIO. PHASE 3. FINAL REPORT
HS-026 400

EVALUATION OF MOTOR VEHICLE EMISSIONS INSPECTION AND MAINTENANCE PROGRAMS IN OHIO. PHASE 2. FINAL REPORT
HS-026 414

ENERGY

SUBCOMPACT VEHICLE ENERGY ABSORBING STEERING COLUMN EVALUATION AND IMPROVEMENT. EXECUTIVE SUMMARY. FINAL REPORT
HS-805 073

SUBCOMPACT VEHICLE ENERGY ABSORBING STEERING COLUMN EVALUATION AND IMPROVEMENT. VOL. 1: ANALYSIS OF ACCIDENT DATA, ENGINEER'S POINT OF VIEW. INTERIM REPORT
HS-805 074

SUBCOMPACT VEHICLE ENERGY ABSORBING STEERING COLUMN EVALUATION AND IMPROVEMENT. VOL. 2: ANALYSIS OF ACCIDENT DATA, STATISTICIAN/ANALYST'S POINT OF VIEW. INTERIM REPORT
HS-805 075

SUBCOMPACT VEHICLE ENERGY ABSORBING STEERING COLUMN EVALUATION AND IMPROVEMENT. VOL. 3: APPENDICES. INTERIM REPORT
HS-805 076

ENFORCEMENT

ADMINISTRATOR'S GUIDE TO SPEED ENFORCEMENT/PATROL CONFIGURATIONS FOR THE NATIONAL MAXIMUM SPEED LIMIT (NMSL). FINAL REPORT
HS-805 150

NATIONAL MAXIMUM SPEED LIMIT (NMSL) ENFORCEMENT PRACTICES AND PROCEDURES, PHASE 2. INTERIM REPORT
HS-805 149

ENGINEER

SUBCOMPACT VEHICLE ENERGY ABSORBING STEERING COLUMN EVALUATION AND IMPROVEMENT. VOL. 1: ANALYSIS OF ACCIDENT DATA, ENGINEER'S POINT OF VIEW. INTERIM REPORT
HS-805 074

EPIDEMIOLOGY

EPIDEMIOLOGY OF CHILDHOOD MOTOR VEHICLE RELATED ACCIDENTS
HS-027 531

EQUIPMENT

SAFETY RELATED RECALL CAMPAIGNS FOR MOTOR VEHICLES AND MOTOR VEHICLE EQUIPMENT, INCLUDING TIRES, REPORTED TO THE NATIONAL HIGHWAY TRAFFIC SAFETY ADMINISTRATION BY DOMESTIC AND FOREIGN VEHICLE MANUFACTURERS, JANUARY 1, 1979 TO MARCH 31, 1979
HS-804 472

EQUIPPED

SMALL CAR DRIVER INFLATABLE RESTRAINT SYSTEM EVALUATION. VOL. 3: INVESTIGATION OF POTENTIAL CRASH SURVIVABILITY OF A CURRENT PRODUCTION SUBCOMPACT VEHICLE EQUIPPED WITH AN ADVANCED DRIVER RESTRAINT SYSTEM. FINAL REPORT.
HS-805 054

EQUIVALENT

COMPARISON OF PASSENGER INJURIES IN FRONTAL CAR COLLISIONS WITH DUMMY LOADINGS IN EQUIVALENT SIMULATIONS
HS-027 528

ERRORS

TRI-LEVEL STUDY: MODIFICATION, TASK 5. AN EXAMINATION OF DRIVER CHARACTERISTICS AND COLLISION PRODUCING ERRORS OF ACCIDENT AND TRAFFIC VIOLATION REPEATERS. FINAL REPORT
HS-805 097

ESTABLISHMENT

ESTABLISHMENT OF THE REPEATABILITY OF PERFORMANCE OF THE SA103C THREE-YEAR OLD CHILD TEST DUMMIES. FINAL REPORT
HS-805 071

ESTES

DEBATE BETWEEN SECRETARY ADAMS AND GM PRESIDENT ESTES. MAC NEIL/LEHRER REPORT, MAY 28, 1979
HS-026 396

ESTIMATES

MOTOR VEHICLE TRAFFIC FATALITIES IN THE UNITED STATES. TRENDS FROM 1975 TO 1978 AND 1979 4-MONTH ESTIMATES
HS-804 783

ESTIMATION

NATIONAL SYMPOSIUM ON COMMERCIAL TRUCK EXPOSURE ESTIMATION. VOL. 2: PROCEEDINGS. FINAL REPORT
HS-805 122

ETOBICOKE

R.I.D.E. (REDUCE IMPAIRED DRIVING IN ETOBICOKE): A PREVENTION PROGRAMME FOR DRINKING DRIVING
HS-027 610

EVALUATED

DRINKING-DRIVER PROBATION SHOULD BE EVALUATED FROM A PROBATION PERSPECTIVE
HS-027 599

EVALUATION

CHILD RESTRAINT EVALUATION BY EXPERIMENTAL AND MATHEMATICAL SIMULATION
HS-027 535

DEVELOPMENT AND EVALUATION OF A TRAFFIC SAFETY AND ALCOHOL PROGRAM FOR SENIOR ADULTS
HS-027 612

DEVELOPMENT OF TESTING AND EVALUATION OF CHILD RESTRAINT SYSTEMS AND CHILD TEST DUMMIES BY NHTSA (NATIONAL HIGHWAY TRAFFIC SAFETY ADMINISTRATION)
HS-027 536

EVALUATION OF A NONCONTACT DISPLACEMENT GAGE FOR MEASUREMENT OF ANTHROPOMORPHIC DUMMY CHEST DEFLECTION. FINAL REPORT
HS-805 123

EVALUATION OF HIGHWAY ADVISORY RADIO IN THE I-35W TRAFFIC MANAGEMENT NETWORK. FINAL REPORT
HS-026 393

EVALUATION OF HUMAN TOLERANCE IN FRONTAL IMPACTS
HS-027 550

EVALUATION OF MOTOR VEHICLE EMISSIONS INSPECTION AND MAINTENANCE PROGRAMS IN OHIO. PHASE 3. FINAL REPORT
HS-026 400

EVALUATION OF MOTOR VEHICLE EMISSIONS INSPECTION AND MAINTENANCE PROGRAMS IN OHIO. PHASE 2. FINAL REPORT
HS-026 414

EVALUATION OF THE MULLARD/TRRL (TRANSPORT AND ROAD RESEARCH LABORATORY) ANTI-LOCK BRAKE SYSTEM. FINAL REPORT
HS-804 192

FIELD TEST EVALUATION OF REAR LIGHTING DECELERATION SIGNALS: 1. ANALYTICAL AND EXPERIMENTAL STUDIES. INTERIM REPORT
HS-805 061

HIGHWAY TRAFFIC SAFETY MANAGEMENT ORIENTATION MODULE DEVELOPMENT. ADMINISTRATIVE EVALUATION. FINAL TECHNICAL REPORT
HS-805 069

IMPLEMENTATION OF A LARGE SCALE REHABILITATION PROGRAM EVALUATION (DRUNK DRIVING OFFENDERS)
HS-027 601

NATIONAL DRIVER REGISTER (NDR) ALTERNATIVE PROGRAM COST EVALUATION. FINAL REPORT
HS-805 120

NATIONAL DRIVER REGISTER (NDR) ALTERNATIVE PROGRAM COST EVALUATION. PT. 2. FINAL REPORT
HS-805 129

NEW AND REBUILT BRAKE MASTER CYLINDER SURVEY AND PERFORMANCE EVALUATION. FINAL REPORT
HS-805 101

REHABILITATION EFFECTIVENESS FOR SAFE PROJECT DRIVERS RECEIVING DEFENSIVE DRIVING COURSE TRAINING. A SUPPLEMENTAL EVALUATION REPORT. FINAL REPORT
HS-804 777

SMALL CAR DRIVER INFLATABLE RESTRAINT SYSTEM EVALUATION. VOL. 3: INVESTIGATION OF POTENTIAL CRASH SURVIVABILITY OF A CURRENT PRODUCTION SUBCOMPACT VEHICLE EQUIPPED WITH AN ADVANCED DRIVER RESTRAINT SYSTEM. FINAL REPORT.
HS-805 054

SMALL CAR DRIVER INFLATABLE RESTRAINT SYSTEM EVALUATION. VOL. 4. EVOLVING A LOW MOUNT PASSENGER AIR CUSHION RESTRAINT SYSTEM (ACRS) FOR THE VEGA SUBCOMPACT VEHICLE. FINAL REPORT
HS-805 055

STATE PMVI (PERIODIC MOTOR VEHICLE INSPECTION) PROGRAM EVALUATION. FINAL REPORT
HS-804 127

SUBCOMPACT VEHICLE ENERGY ABSORBING STEERING COLUMN EVALUATION AND IMPROVEMENT. EXECUTIVE SUMMARY. FINAL REPORT

BASELINE TEST OF COMPACT VEHICLE SIDE STRUCTURE, 35 MPH, 90 DEGREE IMPACT, TORINO-TO-VOLARE, TEST NO. 9. FINAL REPORT
HS-803 787

BIODYNAMICS OF THE LIVING HUMAN SPINE DURING -GX IMPACT ACCELERATION
HS-027 545

HEAD IMPACT RESPONSE COMPARISONS OF HUMAN SURROGATES
HS-027 538

IMPACT OF FMVSS 208 COMFORT AND CONVENIENCE ON VEHICLE MANUFACTURING. FINAL REPORT
HS-805 135

IMPACT TEST OF COMPACT VEHICLE WITH MODIFIED SIDE STRUCTURE, 25 MPH, 60 DEGREE IMPACT, TORINO-TO-VOLARE, TEST NO. 3. FINAL REPORT
HS-803 781

IMPACT TEST OF COMPACT VEHICLE WITH MODIFIED SIDE STRUCTURE, 35 MPH, 90 DEGREE IMPACT, TORINO-TO-VOLARE, TEST NO. 4. FINAL REPORT
HS-803 782

IMPACT TEST OF COMPACT VEHICLE WITH MODIFIED SIDE STRUCTURE, 35 MPH, 60 DEGREE IMPACT, TORINO-TO-VOLARE, TEST NO. 6. FINAL REPORT
HS-803 784

IMPACT TEST OF COMPACT VEHICLE WITH MODIFIED SIDE STRUCTURE, 35 MPH, 60 DEGREE IMPACT, TORINO-TO-VOLARE, TEST NO. 7. FINAL REPORT
HS-803 785

IMPACT TEST OF COMPACT VEHICLE WITH MODIFIED SIDE STRUCTURE, 35 MPH, 90 DEGREE IMPACT, TORINO-TO-VOLARE, TEST NO. 8. FINAL REPORT
HS-803 786

IMPACT TEST OF COMPACT VEHICLE WITH MODIFIED SIDE STRUCTURE, 35 MPH, 90 DEGREE IMPACT, IMPALA-TO-VOLARE, TEST NO. 11. FINAL REPORT
HS-803 789

MODIFICATION OF PART 572 DUMMY FOR LATERAL IMPACT ACCORDING TO BIOMECHANICAL DATA
HS-027 549

POSTURAL INFLUENCES ON THORACIC IMPACT
HS-027 546

RESPONSE OF BELT RESTRAINED SUBJECTS IN SIMULATED LATERAL IMPACT
HS-027 524

SIMULATION OF SIDE IMPACT USING THE CAL3D OCCUPANT SIMULATION MODEL
HS-027 526

TRAFFIC SAFETY IMPACT OF MANDATED LICENSING ACTIONS RELATIVE TO ALCOHOL ABUSE TREATMENT PROGRAMS OR FINES AND/OR JAIL SANCTIONS
HS-027 600

IMPACTS

EVALUATION OF HUMAN TOLERANCE IN FRONTAL IMPACTS
HS-027 550

IMPAIRED

R.I.D.E. (REDUCE IMPAIRED DRIVING IN ETOBICOKE): A PREVENTION PROGRAMME FOR DRINKING DRIVING
HS-027 610

IMPALA

IMPACT TEST OF COMPACT VEHICLE WITH MODIFIED SIDE STRUCTURE, 35 MPH, 90 DEGREE IMPACT, IMPALA-TO-VOLARE, TEST NO. 11. FINAL REPORT
HS-803 789

IMPLEMENTATION

CRITERIA FOR IMPLEMENTATION OF OPTIMUM INTEGRATION ALGORITHM INTO THE WRECKER PROGRAM. VOL. 1: SUMMARY FINAL REPORT [VEHICLE STRUCTURAL DYNAMICS]
HS-805 083

CRITERIA FOR IMPLEMENTATION OF OPTIMUM INTEGRATION ALGORITHM INTO THE WRECKER PROGRAM. VOL. 2: FINAL TECHNICAL REPORT [VEHICLE STRUCTURAL DYNAMICS]
HS-805 084

IMPLEMENTATION OF A LARGE SCALE REHABILITATION PROGRAM EVALUATION (DRUNK DRIVING OFFENDERS)
HS-027 601

IMPLIED

AN HONEST IMPLIED CONSENT LAW (DRIVING WHILE INTOXICATED OFFENSES)
HS-027 607

IMPROVE

FEASIBILITY OF DEVELOPING TRAINING PROGRAMS DESIGNED TO IMPROVE DEFICIENT DRIVER FACTORS. VOL. 1: A REVIEW OF EXISTING DATA BASES AND RECOMMENDATIONS FOR FUTURE DATA COLLECTION. FINAL REPORT
HS-804 746

FEASIBILITY OF DEVELOPING TRAINING PROGRAMS DESIGNED TO IMPROVE DEFICIENT DRIVER FACTORS. VOL. 2: IDENTIFYING ACCIDENT AVOIDANCE BEHAVIORS: A GUIDE FOR ACCIDENT INVESTIGATORS. FINAL REPORT
HS-804 747

STUDY AND TEST TO CONFIRM AUTOMOBILE DRIVETRAIN COMPONENTS TO IMPROVE FUEL ECONOMY. VOL. 2. THE DRIVETRAIN DESIGN PROCESS WITH AN AUTOMATIC TRANSMISSION. INTERIM REPORT
HS-803 856

IMPROVEMENT

SUBCOMPACT VEHICLE ENERGY ABSORBING STEERING COLUMN EVALUATION AND IMPROVEMENT. EXECUTIVE SUMMARY. FINAL REPORT
HS-805 073

SUBCOMPACT VEHICLE ENERGY ABSORBING STEERING COLUMN EVALUATION AND IMPROVEMENT. VOL. 1: ANALYSIS OF ACCIDENT DATA, ENGINEER'S POINT OF VIEW. INTERIM REPORT
HS-805 074

SUBCOMPACT VEHICLE ENERGY ABSORBING STEERING COLUMN EVALUATION AND IMPROVEMENT. VOL. 2: ANALYSIS OF ACCIDENT DATA, STATISTICIAN/ANALYST'S POINT OF VIEW. INTERIM REPORT
HS-805 075

SUBCOMPACT VEHICLE ENERGY ABSORBING STEERING COLUMN EVALUATION AND IMPROVEMENT. VOL. 3: APPENDICES. INTERIM REPORT
HS-805 076

IMPROVEMENTS

TRI-LEVEL STUDY: MODIFICATION, TASK 1. FINAL REPORT ON POTENTIAL BENEFITS OF VARIOUS IMPROVEMENTS IN VEHICLE SYSTEMS IN PREVENTING ACCIDENTS OR REDUCING THEIR SEVERITY
HS-805 094

INCIDENT

ALTERNATIVE SURVEILLANCE CONCEPTS AND METHODS FOR FREEWAY INCIDENT MANAGEMENT. VOL. 1: EXECUTIVE SUMMARY. FINAL REPORT
HS-026 413

INCREASING

DEVELOPMENT AND TESTING OF TECHNIQUES FOR INCREASING THE CONSPICUITY OF MOTORCYCLES AND MOTORCYCLE DRIVERS. FINAL REPORT
HS-805 143

INDEPENDENT

THE NATIONAL PARTS RETURN PROGRAM. VOL. 1: INDEPENDENT REPAIR FACILITIES. FINAL REPORT
HS-805 144

INDUCED

ACCELERATION INDUCED SHEAR STRAINS IN A MONKEY BRAIN HEMISECTION
HS-027 541

DIFFERENTIAL TOLERANCE OF FRONTAL AND TEMPORAL LOBES TO CONTUSION INDUCED BY ANGULAR ACCELERATION
HS-027 540

INFLATABLE

SMALL CAR DRIVER INFLATABLE RESTRAINT SYSTEM EVALUATION. VOL. 3: INVESTIGATION OF POTENTIAL CRASH SURVIVABILITY OF A CURRENT PRODUCTION SUBCOMPACT VEHICLE EQUIPPED WITH AN ADVANCED DRIVER RESTRAINT SYSTEM. FINAL REPORT.
HS-805 054

SMALL CAR DRIVER INFLATABLE RESTRAINT SYSTEM EVALUATION. VOL. 4. EVOLVING A LOW MOUNT PASSENGER AIR CUSHION RESTRAINT SYSTEM (ACRS) FOR THE VEGA SUBCOMPACT VEHICLE. FINAL REPORT
HS-805 055

INFLATING

A STUDY OF DRIVER INTERACTIONS WITH AN INFLATING AIR CUSHION
HS-027 547

INFLUENCES

POSTURAL INFLUENCES ON THORACIC IMPACT
HS-027 546

INFORMATION

ALCOHOL/SAFETY PUBLIC INFORMATION MATERIALS CATALOG. NUMBER 3. SUPPLEMENT 3
HS-804 785

CORPORATE STRATEGIES OF THE AUTOMOTIVE MANUFACTURERS. VOL. 3: PANORAMA OF SELECTED ECONOMIC AND OPERATING INFORMATION. FINAL REPORT
HS-804 587

RESTRAINT SYSTEM/SPEED LIMIT PUBLIC INFORMATION MATERIALS CATALOG. NUMBER 1. SUPPLEMENT 1
HS-804 784

INJECTION

A STRATEGY FOR OPTIMIZATION OF DIESEL FUEL INJECTION SYSTEM
HS-026 398

INJURIES

COMPARISON OF PASSENGER INJURIES IN FRONTAL CAR COLLISIONS WITH DUMMY LOADINGS IN EQUIVALENT SIMULATIONS
HS-027 528

EXPERIMENTAL AUTOMOBILE-PEDESTRIAN INJURIES
HS-026 411

INFLUENCE OF MASS RATIO AND STRUCTURAL COMPATIBILITY ON THE SEVERITY OF INJURIES SUSTAINED BY THE NEAR SIDE OCCUPANTS IN CAR-TO-CAR SIDE COLLISIONS
HS-027 529

INJURIES TO PEDESTRIANS IN REAL ACCIDENTS AND THEIR RELATION TO COLLISION AND CAR CHARACTERISTICS
HS-027 527

LATENT STRUCTURE MODELS APPLIED TO THE JOINT DISTRIBUTION OF DRIVERS' INJURIES IN ROAD ACCIDENTS
HS-026 399

SOME FACTORS INFLUENCING THE INJURIES SUSTAINED BY CHILD PEDESTRIANS STRUCK BY THE FRONTS OF CARS
HS-027 534

INJURY

INJURY MECHANISMS TO FULLY RESTRAINED OCCUPANTS
HS-027 522

MOPED, MINIBIKE, AND MOTORCYCLE ACCIDENTS. ASSOCIATED INJURY PROBLEMS
HS-026 392

THE RESPONSE OF UNEMBALMED CADAVERIC AND LIVING CEREBRAL VESSELS TO GRADED INJURY--A PILOT STUDY
HS-027 539

INNOVATION

CASE STUDY OF THE INNOVATION PROCESS CHARACTERIZING THE DEVELOPMENT OF THE THREE-WAY CATALYTIC CONVERTER SYSTEM. FINAL REPORT
HS-804 791

INPUT

RESEARCH INPUT FOR COMPUTER SIMULATION OF AUTOMOBILE COLLISIONS. VOL. 2. STAGED COLLISIONS: TESTS NO. 1 THROUGH NO. 5. FINAL REPORT
HS-805 038

RESEARCH INPUT FOR COMPUTER SIMULATION OF AUTOMOBILE COLLISIONS. VOL. 3. STAGED COLLISIONS: TESTS NO. 6 THROUGH NO. 12. FINAL REPORT
HS-805 039

INSPECTION

A MANAGEMENT SYSTEM FOR EVALUATING TRAILER/MOTORCYCLE, AUTO/TRUCK, AND REJECTION RECEIPTS IN THE VIRGINIA PERIODIC MOTOR VEHICLE INSPECTION PROGRAM. FINAL REPORT
HS-026 401

CORRELATION OF BRAKING SYSTEM DEFECTS AND PERFORMANCE INSPECTION. VOL. 1: SUMMARY REPORT. FINAL REPORT
HS-805 125

CORRELATION OF BRAKING SYSTEM DEFECTS AND PERFORMANCE INSPECTION. VOL. 2: TECHNICAL REPORT. FINAL REPORT
HS-805 126

EVALUATION OF MOTOR VEHICLE EMISSIONS INSPECTION AND MAINTENANCE PROGRAMS IN OHIO. PHASE 3. FINAL REPORT
HS-026 400

EVALUATION OF MOTOR VEHICLE EMISSIONS INSPECTION AND MAINTENANCE PROGRAMS IN OHIO. PHASE 2. FINAL REPORT
HS-026 414

FINANCING OPTIONS FOR DIAGNOSTIC INSPECTION PROGRAMS. FINAL REPORT
HS-805 147

OPTIMUM FREQUENCY OF INSPECTION. FINAL REPORT (BRAKE SYSTEM COMPONENTS)
HS-804 723

STATE PMVI (PERIODIC MOTOR VEHICLE INSPECTION) PROGRAM EVALUATION. FINAL REPORT
HS-804 127

INSTRUCTOR

EMERGENCY MEDICAL SERVICES INSTRUCTOR TRAINING COURSE
HS-900 031

INTEGRATED
PROTECTION OF OCCUPANTS OF COMMERCIAL VEHICLES BY INTEGRATED SEAT/BELT SYSTEMS
HS-027 521

INTEGRATION
CRITERIA FOR IMPLEMENTATION OF OPTIMUM INTEGRATION ALGORITHM INTO THE WRECKER PROGRAM. VOL. 1: SUMMARY FINAL REPORT [VEHICLE STRUCTURAL DYNAMICS]
HS-805 083

CRITERIA FOR IMPLEMENTATION OF OPTIMUM INTEGRATION ALGORITHM INTO THE WRECKER PROGRAM. VOL. 2: FINAL TECHNICAL REPORT [VEHICLE STRUCTURAL DYNAMICS]
HS-805 084

INTERACTION
CHARACTERIZATION OF WHEEL-ROADWAY INTERACTION FOR RECREATIONAL VEHICLES
HS-026 403

INTERACTIONS
A STUDY OF DRIVER INTERACTIONS WITH AN INFLATING AIR CUSHION
HS-027 547

INTERIM
FIELD TEST EVALUATION OF REAR LIGHTING DECELERATION SIGNALS: 1. ANALYTICAL AND EXPERIMENTAL STUDIES. INTERIM REPORT
HS-805 061

NATIONAL MAXIMUM SPEED LIMIT (NMSL) ENFORCEMENT PRACTICES AND PROCEDURES, PHASE 2. INTERIM REPORT
HS-805 149

STUDY AND TEST TO CONFIRM AUTOMOBILE DRIVETRAIN COMPONENTS TO IMPROVE FUEL ECONOMY. VOL. 2. THE DRIVETRAIN DESIGN PROCESS WITH AN AUTOMATIC TRANSMISSION. INTERIM REPORT

HS-805 098

TEACH

THE CLASS THAT WAS DESIGNED TO TEACH - EACH ONE (DRINKING/DRIVING COUNTERMEASURE PROGRAM FOR ILLITERATE PERSONS)
HS-027 617

TEACHING

PROJECT ADAPTS (ALCOHOL - DRIVERS AND PEOPLE - TEACHING SAFETY)
HS-027 614

TEAM

A TEAM APPROACH TO TRAFFIC SAFETY AND ALCOHOL TREATMENT
HS-027 619

TECHNOLOGY

DEVELOPMENT OF A LOW COST PORTABLE FLUOROMETRY TECHNOLOGY AND QUANTIFICATION OF CANNABINOIDS IN BODY FLUIDS. FINAL REPORT
HS-804 009

THE APPLICATION OF "STATE OF THE ART" INTERVENTION AND EVALUATION TECHNOLOGY: PROSPECTS FOR THE FUTURE OF THE ALCOHOL AND TRAFFIC SAFETY COUNTERMEASURES APPROACH
HS-027 602

TEMPORAL

DIFFERENTIAL TOLERANCE OF FRONTAL AND TEMPORAL LOBES TO CONTUSION INDUCED BY ANGULAR ACCELERATION
HS-027 540

TERMEASURES

TECHNIQUES FOR PREDICTING HIGH-RISK DRIVERS FOR ALCOHOL COUN- TERMEASURES. VOL. 2. USER MANUAL. FINAL REPORT
HS-804 733

TEST

A 30 MPH FRONT/REAR CRASH WITH HUMAN TEST PERSONS
HS-027 548

BASELINE TEST OF COMPACT VEHICLE SIDE STRUCTURE, 25 MPH, 60 DEGREE IMPACT, TORINO-TO-VOLARE, TEST NO. 1
HS-803 779

BASELINE TEST OF COMPACT VEHICLE SIDE STRUCTURE, 35 MPH, 90 DEGREE IMPACT, TORINO-TO-VOLARE, TEST NO. 9. FINAL REPORT
HS-803 787

CALIBRATION AND TEST PROCEDURES FOR THREE YEAR OLD CHILD DUMMY. FINAL REPORT
HS-805 070

DETERMINATION OF TRAILER STABILITY THROUGH SIMPLE ANALYTICAL METHODS AND TEST PROCEDURES
HS-026 408

DEVELOPMENT OF AERODYNAMIC DISTURBANCE TEST PROCEDURES. VOL. 2: TECHNICAL REPORT. FINAL REPORT
HS-805 079

DEVELOPMENT OF TESTING AND EVALUATION OF CHILD RESTRAINT SYSTEMS AND CHILD TEST DUMMIES BY NHTSA (NATIONAL HIGHWAY TRAFFIC SAFETY ADMINISTRATION)
HS-027 536

ESTABLISHMENT OF THE REPEATABILITY OF PERFORMANCE OF THE SA103C THREE-YEAR OLD CHILD TEST DUMMIES. FINAL REPORT
HS-805 071

FIELD TEST EVALUATION OF REAR LIGHTING DECELERATION SIGNALS: 1. ANALYTICAL AND EXPERIMENTAL STUDIES. INTERIM REPORT
HS-805 061

IMPACT TEST OF COMPACT VEHICLE WITH MODIFIED SIDE STRUCTURE, 25 MPH, 60 DEGREE IMPACT, TORINO-TO-VOLARE, TEST NO. 3. FINAL REPORT
HS-803 781

IMPACT TEST OF COMPACT VEHICLE WITH MODIFIED SIDE STRUCTURE, 35 MPH, 90 DEGREE IMPACT, TORINO-TO-VOLARE, TEST NO. 4. FINAL REPORT
HS-803 782

IMPACT TEST OF COMPACT VEHICLE WITH MODIFIED SIDE STRUCTURE, 35 MPH, 60 DEGREE IMPACT, TORINO-TO-VOLARE, TEST NO. 6. FINAL REPORT
HS-803 784

IMPACT TEST OF COMPACT VEHICLE WITH MODIFIED SIDE STRUCTURE, 35 MPH, 60 DEGREE IMPACT, TORINO-TO-VOLARE, TEST NO. 7. FINAL REPORT
HS-803 785

IMPACT TEST OF COMPACT VEHICLE WITH MODIFIED SIDE STRUCTURE, 35 MPH, 90 DEGREE IMPACT, TORINO-TO-VOLARE, TEST NO. 8. FINAL REPORT
HS-803 786

IMPACT TEST OF COMPACT VEHICLE WITH MODIFIED SIDE STRUCTURE, 35 MPH, 90 DEGREE IMPACT, IMPALA-TO-VOLARE, TEST NO. 11. FINAL REPORT
HS-803 789

STUDY AND TEST TO CONFIRM AUTOMOBILE DRIVETRAIN COMPONENTS TO IMPROVE FUEL ECONOMY. VOL. 2. THE DRIVETRAIN DESIGN PROCESS WITH AN AUTOMATIC TRANSMISSION. INTERIM REPORT
HS-803 856

TESTING

ALCOHOL COUNTERMEASURES: ILLEGAL PER SE AND PRELIMINARY BREATH TESTING LAWS. ISSUE PAPER
HS-803 823

DEVELOPMENT AND TESTING OF TECHNIQUES FOR INCREASING THE CONSPICUITY OF MOTORCYCLES AND MOTORCYCLE DRIVERS. FINAL REPORT
HS-805 143

DEVELOPMENT OF TESTING AND EVALUATION OF CHILD RESTRAINT SYSTEMS AND CHILD TEST DUMMIES BY NHTSA (NATIONAL HIGHWAY TRAFFIC SAFETY ADMINISTRATION)
HS-027 536

NDT (NONDESTRUCTIVE TESTING)/ROAD CORRELATION. FINAL TECHNICAL REPORT
HS-805 034

TRI-LEVEL STUDY: MODIFICATION, TASK 6. A FINAL REPORT ON SUPPLEMENTAL CAUSATION ASSESSMENTS THROUGH HYPOTHESIS TESTING
HS-805 098

TESTS

RESEARCH INPUT FOR COMPUTER SIMULATION OF AUTOMOBILE COLLISIONS. VOL. 2. STAGED COLLISIONS: TESTS NO. 1 THROUGH NO. 5. FINAL REPORT
HS-805 038

RESEARCH INPUT FOR COMPUTER SIMULATION OF AUTOMOBILE COLLISIONS. VOL. 3. STAGED COLLISIONS: TESTS NO. 6 THROUGH NO. 12. FINAL REPORT
HS-805 039

TESTS AND MATERIALS FOR SCHOOL BUS RETROFIT APPLICATIONS
HS-027 537

THEFT

VEHICLE ANTI-THEFT SECURITY SYSTEM DESIGN. VOL. 1: SUMMARY REPORT. FINAL REPORT
HS-804 339

VEHICLE ANTI-THEFT SECURITY SYSTEM DESIGN. VOL. 2: FINAL TECHNICAL REPORT
HS-804 340

THORACIC

POSTURAL INFLUENCES ON THORACIC IMPACT
HS-027 546

TIRE

TIRE TREADWARE VALIDATION. VOL. 1: TECHNICAL REPORT. FINAL REPORT
HS-804 792

TIRES

SAFETY RELATED RECALL CAMPAIGNS FOR MOTOR VEHICLES AND MOTOR VEHICLE EQUIPMENT, INCLUDING TIRES, REPORTED TO THE NATIONAL HIGHWAY TRAFFIC SAFETY ADMINISTRATION BY DOMESTIC AND FOREIGN VEHICLE MANUFACTURERS, JANUARY 1, 1979 TO MARCH 31, 1979
HS-804 472

TOLERANCE

DIFFERENTIAL TOLERANCE OF FRONTAL AND TEMPORAL LOBES TO CONTUSION INDUCED BY ANGULAR ACCELERATION
HS-027 540

EVALUATION OF HUMAN TOLERANCE IN FRONTAL IMPACTS
HS-027 550

TORINO

BASELINE TEST OF COMPACT VEHICLE SIDE STRUCTURE, 25 MPH, 60 DEGREE IMPACT, TORINO-TO-VOLARE, TEST NO. 1
HS-803 779

BASELINE TEST OF COMPACT VEHICLE SIDE STRUCTURE, 35 MPH, 90 DEGREE IMPACT, TORINO-TO-VOLARE, TEST NO. 9. FINAL REPORT
HS-803 787

IMPACT TEST OF COMPACT VEHICLE WITH MODIFIED SIDE STRUCTURE, 25 MPH, 60 DEGREE IMPACT, TORINO-TO-VOLARE, TEST NO. 3. FINAL REPORT
HS-803 781

IMPACT TEST OF COMPACT VEHICLE WITH MODIFIED SIDE STRUCTURE, 35 MPH, 90 DEGREE IMPACT, TORINO-TO-VOLARE, TEST NO. 4. FINAL REPORT
HS-803 782

IMPACT TEST OF COMPACT VEHICLE WITH MODIFIED SIDE STRUCTURE, 35 MPH, 60 DEGREE IMPACT, TORINO-TO-VOLARE, TEST NO. 6. FINAL REPORT
HS-803 784

IMPACT TEST OF COMPACT VEHICLE WITH MODIFIED SIDE STRUCTURE, 35 MPH, 60 DEGREE IMPACT, TORINO-TO-VOLARE, TEST NO. 7. FINAL REPORT
HS-803 785

IMPACT TEST OF COMPACT VEHICLE WITH MODIFIED SIDE STRUCTURE, 35 MPH, 90 DEGREE IMPACT, TORINO-TO-VOLARE, TEST NO. 8. FINAL REPORT
HS-803 786

TRACTOR

DATA ANALYSIS OF TRACTOR-TRAILER DRIVERS TO ASSESS DRIVERS' PERCEPTION OF HEAVY DUTY TRUCK RIDE QUALITY. FINAL REPORT
HS-805 139

THE YAW STABILITY OF TRACTOR-SEMITRAILERS DURING CORNERING. FINAL SUMMARY REPORT
HS-805 140

THE YAW STABILITY OF TRACTOR-SEMITRAILERS DURING CORNERING. FINAL REPORT
HS-805 141

TRAFFIC

A TEAM APPROACH TO TRAFFIC SAFETY AND ALCOHOL TREATMENT
HS-027 619

DEVELOPMENT AND EVALUATION OF A TRAFFIC SAFETY AND ALCOHOL PROGRAM FOR SENIOR ADULTS
HS-027 612

DEVELOPMENT OF TESTING AND EVALUATION OF CHILD RESTRAINT SYSTEMS AND CHILD TEST DUMMIES BY NHTSA (NATIONAL HIGHWAY TRAFFIC SAFETY ADMINISTRATION)
HS-027 536

EVALUATION OF HIGHWAY ADVISORY RADIO IN THE I-35W TRAFFIC MANAGEMENT NETWORK. FINAL REPORT
HS-026 393

HIGHWAY TRAFFIC SAFETY MANAGEMENT ORIENTATION MODULE DEVELOPMENT. ADMINIS-

TRATIVE EVALUATION. FINAL TECHNICAL REPORT
HS-805 069

MOTOR VEHICLE TRAFFIC FATALITIES IN THE UNITED STATES. TRENDS FROM 1975 TO 1978 AND 1979 4-MONTH ESTIMATES
HS-804 783

NCA (NATIONAL COUNCIL ON ALCOHOLISM) ALCOHOL AND TRAFFIC SAFETY SESSION (1979) PROCEEDINGS, APRIL 30 THROUGH MAY 2, 1979
HS-804 857

NHTSA (NATIONAL HIGHWAY TRAFFIC SAFETY ADMINISTRATION) CHILD SAFETY ACTIVITIES
HS-027 533

SAFETY RELATED RECALL CAMPAIGNS FOR MOTOR VEHICLES AND MOTOR VEHICLE EQUIPMENT, INCLUDING TIRES, REPORTED TO THE NATIONAL HIGHWAY TRAFFIC SAFETY ADMINISTRATION BY DOMESTIC AND FOREIGN VEHICLE MANUFACTURERS, JANUARY 1, 1979 TO MARCH 31, 1979
HS-804 472

THE APPLICATION OF "STATE OF THE ART" INTERVENTION AND EVALUATION TECHNOLOGY: PROSPECTS FOR THE FUTURE OF THE ALCOHOL AND TRAFFIC SAFETY COUNTERMEASURES APPROACH
HS-027 602

TRAFFIC SAFETY IMPACT OF MANDATED LICENSING ACTIONS RELATIVE TO ALCOHOL ABUSE TREATMENT PROGRAMS OR FINES AND/OR JAIL SANCTIONS
HS-027 600

TRI-LEVEL STUDY OF THE CAUSES OF TRAFFIC ACCIDENTS. VOL. 1: CASUAL FACTOR TABULATIONS AND ASSESSMENTS. FINAL REPORT
HS-805 085

TRI-LEVEL STUDY OF THE CAUSES OF TRAFFIC ACCIDENTS. VOL. 2: SPECIAL ANALYSES. FINAL REPORT
HS-805 086

TRI-LEVEL STUDY OF THE CAUSES OF TRAFFIC ACCIDENTS. EXECUTIVE SUMMARY. FINAL REPORT
HS-805 099

TRI-LEVEL STUDY: MODIFICATION, TASK 5. AN EXAMINATION OF DRIVER CHARACTERISTICS AND COLLISION PRODUCING ERRORS OF ACCIDENT AND TRAFFIC VIOLATION REPEATERS. FINAL REPORT
HS-805 097

TRAILER

A MANAGEMENT SYSTEM FOR EVALUATING TRAILER/MOTORCYCLE, AUTO/TRUCK, AND REJECTION RECEIPTS IN THE VIRGINIA PERIODIC MOTOR VEHICLE INSPECTION PROGRAM. FINAL REPORT
HS-026 401

DATA ANALYSIS OF TRACTOR-TRAILER DRIVERS TO ASSESS DRIVERS' PERCEPTION OF HEAVY DUTY TRUCK RIDE QUALITY. FINAL REPORT
HS-805 139

DETERMINATION OF TRAILER STABILITY THROUGH SIMPLE ANALYTICAL METHODS AND TEST PROCEDURES
HS-026 408

EFFECT OF HITCHPOINT LATERAL STIFFNESS ON TRAILER STABILITY
HS-026 404

TRAINING

EMERGENCY MEDICAL SERVICES INSTRUCTOR TRAINING COURSE
HS-900 031

FEASIBILITY OF DEVELOPING TRAINING PROGRAMS DESIGNED TO IMPROVE DEFICIENT DRIVER FACTORS. VOL. 1: A REVIEW OF EXISTING DATA BASES AND RECOMMENDATIONS FOR FUTURE DATA COLLECTION. FINAL REPORT
HS-804 746

FEASIBILITY OF DEVELOPING TRAINING PROGRAMS DESIGNED TO IMPROVE DEFICIENT DRIVER FACTORS. VOL. 2: IDENTIFYING ACCIDENT AVOIDANCE BEHAVIORS: A GUIDE FOR ACCIDENT INVESTIGATORS. FINAL REPORT
HS-804 747

MULTIDISCIPLINARY HIGHWAY COLLISION INVESTIGATION TRAINING COURSE. FINAL REPORT
HS-805 103

REHABILITATION EFFECTIVENESS FOR SAFE PROJECT DRIVERS RECEIVING DEFENSIVE DRIVING COURSE TRAINING. A SUPPLEMENTAL EVALUATION REPORT. FINAL REPORT
HS-804 777

TRANSFER

DRIVER VISIBILITY QUALITY: AN ELECTRO-OPTICAL METER FOR IN-VEHICLE MEASUREMENT OF MODULATION TRANSFER (MTF). FINAL REPORT
HS-804 105

TRANSMISSION

PURELY HYDROSTATIC HIGH RATIO TRANSMISSION
HS-026 390

STUDY AND TEST TO CONFIRM AUTOMOBILE DRIVETRAIN COMPONENTS TO IMPROVE FUEL ECONOMY. VOL. 2. THE DRIVETRAIN DESIGN PROCESS WITH AN AUTOMATIC TRANSMISSION. INTERIM REPORT
HS-803 856

TRANSMISSIONS

CONTINUOUSLY VARIABLE TRANSMISSIONS FOR CARS WITH HIGH RATIO COVERAGE
HS-026 389

TRANSPORT

EVALUATION OF THE MULLARD/TRRL (TRANSPORT AND ROAD RESEARCH LABORATORY) ANTI-LOCK BRAKE SYSTEM. FINAL REPORT
HS-804 192

TRAUMA

OFF-ROAD VEHICLE ACCIDENTS: A NEW SPECTRUM OF TRAUMA
HS-026 412

TREADWARE

TIRE TREADWARE VALIDATION. VOL. 1: TECHNICAL REPORT. FINAL REPORT
HS-804 792

TREATMENT

A TEAM APPROACH TO TRAFFIC SAFETY AND ALCOHOL TREATMENT
HS-027 619

TRAFFIC SAFETY IMPACT OF MANDATED LICENSING ACTIONS RELATIVE TO ALCOHOL ABUSE TREATMENT PROGRAMS OR FINES AND/OR JAIL SANCTIONS
HS-027 600

TRENDS

MOTOR VEHICLE TRAFFIC FATALITIES IN THE UNITED STATES. TRENDS FROM 1975 TO 1978 AND 1979 4-MONTH ESTIMATES
HS-804 783

TRRL

EVALUATION OF THE MULLARD/TRRL (TRANSPORT AND ROAD RESEARCH LABORATORY) ANTI-LOCK BRAKE SYSTEM. FINAL REPORT
HS-804 192

TRUCK

A MANAGEMENT SYSTEM FOR EVALUATING TRAILER/MOTORCYCLE, AUTO/TRUCK, AND REJECTION RECEIPTS IN THE VIRGINIA PERIODIC MOTOR VEHICLE INSPECTION PROGRAM. FINAL REPORT
HS-026 401

DATA ANALYSIS OF TRACTOR-TRAILER DRIVERS TO ASSESS DRIVERS' PERCEPTION OF HEAVY DUTY TRUCK RIDE QUALITY. FINAL REPORT
HS-805 139

NATIONAL SYMPOSIUM ON COMMERCIAL TRUCK EXPOSURE ESTIMATION. VOL. 2: PROCEEDINGS. FINAL REPORT
HS-805 122

TUESDAY

REMARKS AT 55 MPH NATIONAL MAXIMUM SPEED LIMIT CONFERENCE, REGION 3, BALTIMORE HILTON HOTEL, BALTIMORE, MARYLAND, TUESDAY, MAY 22, 1979
HS-810 353

TUNE

TUNE UP YOUR BIKE FOR RIDING EASE AND SAFETY
HS-026 425

TURNING

A SIMPLIFIED ANALYSIS OF THE STEADY-STATE TURNING OF ARTICULATED VEHICLES
HS-026 407

STEADY TURNING OF TWO-WHEELED VEHICLES
HS-026 409

UNEMBALMED

THE RESPONSE OF UNEMBALMED CADAVERIC AND LIVING CEREBRAL VESSELS TO GRADED INJURY--A PILOT STUDY
HS-027 539

UNITED

AN ANALYSIS OF MOPEDS AS A POTENTIAL SAFETY PROBLEM IN THE UNITED STATES. VOL. 2: DATA ANALYSIS AND USAGE AND ACCIDENT PROJECTIONS. FINAL REPORT
HS-805 036

MOTOR VEHICLE TRAFFIC FATALITIES IN THE UNITED STATES. TRENDS FROM 1975 TO 1978 AND 1979 4-MONTH ESTIMATES
HS-804 783

UNPROTECTED

INTRACRANIAL PRESSURE RELATIONSHIPS IN THE PROTECTED AND UNPROTECTED HEAD
HS-027 542

URBAN

URBAN CROSSING PROBLEMS. FINAL REPORT
HS-805 127

URBAN PEDESTRIAN SAFETY. ISSUE PAPER
HS-803 825

USAGE

AN ANALYSIS OF MOPEDS AS A POTENTIAL SAFETY PROBLEM IN THE UNITED STATES. VOL. 2: DATA ANALYSIS AND USAGE AND ACCIDENT PROJECTIONS. FINAL REPORT
HS-805 036

GENERAL SAFETY BELT USAGE. ISSUE PAPER
HS-803 824

RESTRAINT USAGE AND EFFECTIVENESS ON THE NATIONAL CRASH SEVERITY STUDY
HS-805 151

USER

TECHNIQUES FOR PREDICTING HIGH-RISK DRIVERS FOR ALCOHOL COUN- TERMEASURES. VOL. 2. USER MANUAL. FINAL REPORT
HS-804 733

UTILITY

VEHICLE ACCIDENTS AT MAINTENANCE AND UTILITY WORK ZONES
HS-026 416

UTILIZATION

DPMAS (DRIVER PERFORMANCE MEASUREMENT AND ANALYSIS SYSTEM) UTILIZATION. VEHICLE PARAMETER IDENTIFICATION. FINAL TECHNICAL REPORT.
HS-804 721

FUEL UTILIZATION OF ARTICULATED VEHICLES: EFFECT OF GROSS VEHICLE WEIGHT
HS-026 426

VALIDATION

FURTHER VALIDATION OF THE SIMULATION MODEL OF AUTOMOBILE COLLISIONS PROGRAM
HS-027 543

TIRE TREADWARE VALIDATION. VOL. 1: TECHNICAL REPORT. FINAL REPORT
HS-804 792

VALIDITY

TRI-LEVEL STUDY: MODIFICATION, TASK 3. A VALIDITY ASSESSMENT OF POLICE-REPORTED ACCIDENT DATA. FINAL REPORT
HS-805 087

VARIABLE

CONTINUOUSLY VARIABLE TRANSMISSIONS FOR CARS WITH HIGH RATIO COVERAGE
HS-026 389

VEGA

SMALL CAR DRIVER INFLATABLE RESTRAINT SYSTEM EVALUATION. VOL. 4. EVOLVING A LOW MOUNT PASSENGER AIR CUSHION RESTRAINT SYSTEM (ACRS) FOR THE VEGA SUBCOMPACT VEHICLE. FINAL REPORT
HS-805 055

VEHICLE

A MANAGEMENT SYSTEM FOR EVALUATING TRAILER/MOTORCYCLE, AUTO/TRUCK, AND REJECTION RECEIPTS IN THE VIRGINIA PERIODIC MOTOR VEHICLE INSPECTION PROGRAM. FINAL REPORT
HS-026 401

A RECREATION VEHICLE FOR YOUR FAMILY. PT. 2 OF A TWO-PART SERIES ON RECREATIONAL VEHICLES (RV'S)
HS-026 423

BASELINE TEST OF COMPACT VEHICLE SIDE STRUCTURE, 25 MPH, 60 DEGREE IMPACT, TORINO-TO-VOLARE, TEST NO. 1
HS-803 779

BASELINE TEST OF COMPACT VEHICLE SIDE STRUCTURE, 35 MPH, 90 DEGREE IMPACT, TORINO-TO-VOLARE, TEST NO. 9. FINAL REPORT
HS-803 787

CRITERIA FOR IMPLEMENTATION OF OPTIMUM INTEGRATION ALGORITHM INTO THE WRECKER PROGRAM. VOL. 1: SUMMARY FINAL REPORT [VEHICLE STRUCTURAL DYNAMICS]

A STRATEGY FOR OPTIMIZATION OF DIESEL FUEL INJECTION SYSTEM
HS-026 398

Robert Whorf and Associates, 8215 Cedar Rd., Elkins Park, Pa. 19117
MANUFACTURER'S POLICIES CONCERNING AVERAGE FUEL ECONOMY STANDARDS. FINAL REPORT
HS-803 720

Science Applications, Inc., 1801 Ave. of the Stars, Suite 1205, Los Angeles, Calif. 90067
LONG LIFE HYDRAULIC BRAKE SYSTEM. FINAL TECHNICAL REPORT
HS-805 067

Society of Automotive Engineers, Inc., 400 Commonwealth Drive, Warrendale, pa. 15096
STAPP CAR CRASH CONFERENCE (23RD) PROCEEDINGS, OCTOBER 17-19, 1979, SAN DIEGO, CALIFORNIA
HS-027 520

Society of Automotive Engineers, 400 Commonwealth Drive, Warrendale, Pa. 15096
DYNAMICS OF WHEELED RECREATIONAL VEHICLES
HS-026 402

South Coast Technology, Inc., P.O. Box 3265, Santa Barbara, Calif. 93105
ADVANCED MOTORCYCLE HANDLING AND DYNAMICS. VOL. 2, FINAL TECHNICAL REPORT
HS-804 911

ADVANCED MOTORCYCLE HANDLING AND DYNAMICS. VOL. 3, APPENDIX A, DESCRIPTION OF COMPUTER PROGRAMS. FINAL REPORT
HS-804 913

Stanford Univ., Dept. of Mechanical Engineering, Stanford, Calif.
CHARACTERIZATION OF WHEEL-ROADWAY INTERACTION FOR RECREATIONAL VEHICLES
HS-026 403

STEADY TURNING OF TWO-WHEELED VEHICLES
HS-026 409

Systems Technology, Inc., Hawthorne, Calif.
DETERMINATION OF TRAILER STABILITY THROUGH SIMPLE ANALYTICAL METHODS AND TEST PROCEDURES
HS-026 408

Systems Technology, Inc., 13766 South Hawthorne Blvd., Hawthorne, Calif. 90250
THE EFFECTS OF ALCOHOL ON THE DRIVER'S DECISION-MAKING BEHAVIOR. VOL. 2: APPENDICES. FINAL REPORT
HS-803 609

Systems Technology, Inc., 13766 South Hawthorne Blvd., Hawthorne, Calif. 90250
MOTORCYCLE HANDLING. VOL. 1: SUMMARY REPORT. FINAL REPORT
HS-804 190

MOTORCYCLE HANDLING. VOL. 2: TECHNICAL REPORT. FINAL REPORT
HS-804 191

Systems Technology, Inc., 13766 South Hawthorne Blvd., Hawthorne, Calif. 90250
EVALUATION OF THE MULLARD/TRRL (TRANSPORT AND ROAD RESEARCH LABORATORY) ANTI-LOCK BRAKE SYSTEM. FINAL REPORT
HS-804 192

DEVELOPMENT OF AERODYNAMIC DISTURBANCE TEST PROCEDURES. VOL. 2: TECHNICAL REPORT. FINAL REPORT
HS-805 079

Tampa-Hillsborough, Inc., D.W.I. Counterattack School, Tampa, Fla.
THE CLASS THAT WAS DESIGNED TO TEACH - EACH ONE (DRINKING/DRIVING COUNTERMEASURE PROGRAM FOR ILLITERATE PERSONS)
HS-027 617

Technical Univ. of Berlin, Inst. of Automotive Engineering
COMPARISON OF PASSENGER INJURIES IN FRONTAL CAR COLLISIONS WITH DUMMY LOADINGS IN EQUIVALENT SIMULATIONS
HS-027 528

Technical Univ. Berlin, Inst. for Automotive Engineering, Berlin, Germany
SEAT DESIGN--A SIGNIFICANT FACTOR FOR SAFETY BELT EFFECTIVENESS
HS-027 523

Teknekron, Inc., 1483 Chain Bridge Rd., McLean, Va. 22101
OCCUPANT RESTRAINT LEGISLATION HANDBOOK: A GUIDE FOR PROPONENTS. FINAL REPORT
HS-804 780

Transport and Road Res. Lab., Transport Engineering Div., Crowthorne, Berks., England
FUEL UTILIZATION OF ARTICULATED VEHICLES: EFFECT OF GROSS VEHICLE WEIGHT
HS-026 426

U.E.R. Saints Peres, Laboratoire d'Anatomie, Paris, France
A COMPARISON BETWEEN PART 572 DUMMY AND HUMAN SUBJECT IN THE PROBLEM OF SUBMARINING
HS-027 544

Ultrasystems, Inc., 2400 Michelson Drive, Irvine, Calif. 92715
OPTIMUM FREQUENCY OF INSPECTION. FINAL REPORT (BRAKE SYSTEM COMPONENTS)
HS-804 723

University of Birmingham, Dept. of Transportation and Environmental Planning, Birmingham, England
SOME FACTORS INFLUENCING THE INJURIES SUSTAINED BY CHILD PEDESTRIANS STRUCK BY THE FRONTS OF CARS
HS-027 534

University of California at Los Angeles, Alcohol Res. Center, Los Angeles, Calif.
CHARACTERISTICS OF DWI'S (DRIVING WHILE INTOXICATED), ALCOHOLICS, AND CONTROLS
HS-027 598

University of California, Dept. of Pathology, San Diego, Calif.
RESPONSE OF BELT RESTRAINED SUBJECTS IN SIMULATED LATERAL IMPACT
HS-027 524

University of California, San Diego Univ. Hosp.
INTRACRANIAL PRESSURE RELATIONSHIPS IN THE PROTECTED AND UNPROTECTED HEAD
HS-027 542

University of California, San Diego, Dept. of Surgery
THE RESPONSE OF UNEMBALMED CADAVERIC AND LIVING CEREBRAL VESSELS TO GRADED INJURY--A PILOT STUDY
HS-027 539

University of Cincinnati, Engineering Science Dept., Cincinnati, Ohio
OFF-ROAD STABILITY OF RECREATIONAL VEHICLES
HS-026 410

University of Glasgow, Glasgow, Scotland
DIFFERENTIAL TOLERANCE OF FRONTAL AND TEMPORAL LOBES TO CONTUSION INDUCED BY ANGULAR ACCELERATION
HS-027 540

University of Illinois at Urbana-Champaign
EFFECTS OF ALCOHOL AND DIAZEPAM, SINGLY AND IN COMBINATION, ON SOME DRIVING PERFORMANCES
HS-027 611

University of Illinois, Dept. of Health and Safety Education, Champaign, Ill. 61820
FIELD TEST EVALUATION OF REAR LIGHTING DECELERATION SIGNALS: 1. ANALYTICAL AND EXPERIMENTAL STUDIES. INTERIM REPORT
HS-805 061

University of Kentucky, Lexington, Ky.
EFFECT OF HITCHPOINT LATERAL STIFFNESS ON TRAILER STABILITY
HS-026 404

University of Michigan, Hwy. Safety Res. Inst.
CHILD RESTRAINT EVALUATION BY EXPERIMENTAL AND MATHEMATICAL SIMULATION

NOTICE

The March and April issues of Highway Safety Literature are being issued before the February one. This is due to a delay caused by changing one of the contractors and computers used in processing the journal. We expect that the February issue will be available shortly, and that future issues will appear in chronological order.

Highway Safety Literature

U.S. Department of Transportation National Highway Traffic Safety Administration

TD 8.10:

NOTICE

Highway Safety Literature is a monthly publication of the National Highway Traffic Safet Administration (NHTSA). It is divided into the following sections: Abstract Citations, containin bibliographical information and abstracts; and an Index to Abstracts, including a keyword-out-o context (KWOC) list of words in the title, followed by the full title and HS number (our accessio number); an Author Index; a Corporate Author Index; a Contract Number Index; and a Repor Number Index. In those months when information on contracts recently awarded is available, section entitled Contracts Awarded is added at the back.

Abstracts appearing in **Highway Safety Literature** represent documents acquired by the Technica Reference Division, NHTSA. Documents related to the mission of NHTSA may be sent to the Edito at the address below for inclusion in the collection and abstracting in this publication. Pleas indicate availability source and price for each document.

Note: Publication of articles or abstracts in Highway Safety Literature is intended only for infor mation. Views expressed are those of the authors and not necessarily those of the Administra tion. Reference to brand names, equipment, models or companies does not imply endorsement b NHTSA or the U.S. Department of Transportation.

Comments on the articles appearing in **Highway Safety Literature** may be addressed to

AVAILABILITY OF DOCUMENTS

Documents listed in *Highway Safety Literature* are not available from the National Highway Traffic Safety Administration unless so specified. They must be ordered from the sources indicated on the citations, usually at cost. Ordering information for the most common sources is given below.

NTIS: National Technical Information Service, Springfield, Va. 22161. **Order by title and accession number: PB, AD, or HS.** When no PB number is given for NHTSA Technical Reports, order by prefacing the HS number with DOT, i.e. DOT-HS-000 000.

GPO: Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. **Give corporate author, title, personal author, and catalog or stock number.**

Reference copy only: Documents may be examined at the NHTSA Technical Reference Division or borrowed on inter-library loan through your local library.

See publication: Articles in journals, papers in proceedings, or chapters in books are found in the publication cited. These publications may be in libraries or purchased from publishers or dealers.

SAE: Society of Automotive En gineers, Dept. HSL, 400 Com monwealth Drive, Warrendale Pa. 15096. Order by title and SAE report number.

TRB: Transportation Researc Board, National Academy o Sciences, 2101 Constitution Ave. N.W., Washington, D.C. 20418.

Corporate author: Inquiries shoul be addressed to the organizatio listed in the individual citation.

ABSTRACT CITATIONS

SAMPLE ENTRIES

FORMAT OF ENTRIES IN HIGHWAY SAFETY LITERATURE

NHTSA accession number	HS-013 124
Title of document	**MAXIMUM BRAKE PEDAL FORCES PRODUCED MALE AND FEMALE DRIVERS**
Abstract	The object of this research was to obtain data concerning maximum amount of brake pedal force that automobile dri were able to sustain over a period of ten seconds. Sub were told to apply the brakes in the test car as they would panic stop, and to exert as much force as possible on pedal over the entire ten second test period. A total of 84 jects were tested, including 42 males and 42 females. results indicated that there is a wide distribution of va which characterizes the pedal force that the subjects were to generate. Male subjects produced generally higher fo than did females. Over half the women tested were unab exert more than 150 lbs. of force with either foot alone, when both feet were applied to the pedal, force levels rose nificantly.

NHTSA accession number	HS-018 924
Title of document	**NATURAL FREQUENCIES OF THE BIAS TIRE**
Abstract	The lowest natural frequencies of a bias tire under infla pressure are deduced by assuming the bias tire as a compo structure of a bias-laminated, toroidal membrane shell rigorously taking three displacement components into c sideration. The point collocation method is used to solv derived system of differential equations with variable co cients. It is found that the lowest natural frequencies ca lated for two kinds of bias tire agree well with the correspo ing experimental results in a wide range of inflation pressu Results of the approximate analysis show that the influer of the in-plane inertia forces on natural frequency may be c sidered small, but the influences of in-plane displacements large, particularly on the natural frequency of the tire ur low inflation pressure.

COORDINATING TRANSPORTATION SERVICES FOR THE ELDERLY AND HANDICAPPED. STATUTORY AND REGULATORY ANALYSIS OF INCENTIVES AND BARRIERS TO COORDINATING TRANSPORTATION SERVICES FOR THE ELDERLY AND HANDICAPPED. FINAL REPORT

The nature and extent of legislative and regulatory incentives and barriers to the coordination of transportation services for the elderly and the handicapped are examined. In the context of the report, coordination of transportation means sharing existing transportation resources through interagency cooperative agreements. Federal statutes and related regulations are analyzed to discover the incentives or barriers to coordination found in requirements which are related to funding, planning and the provision of transportation services.

COORDINATING TRANSPORTATION SERVICES FOR THE ELDERLY AND HANDICAPPED. A MODEL UNIFORM BILLING AND ACCOUNTING SYSTEM FOR COORDINATED TRANSPORTATION SYSTEMS. FINAL REPORT

A model billing and accounting system, useful to local agencies and organizations attempting to coordinate their transportation services, addresses the common administrative problems (and barriers to coordination) of accounting, allocation/billing, and certification of funding sources. In addition, an analysis of the federal regulations pertaining to fiscal management procedures is provided. Appended are uniform Federal administrative requirements and cost principles, analysis of regulations on uniform administrative requirements, and interviews conducted at the Federal level.

CANADIANS LEARN TO LIVE WITH SEAT BELTS

Use of safety belt systems became mandatory in Ontario and Quebec in 1976 and in Saskatchewan and British Columbia in Oct 1977. These provinces represent a substantial majority of the Canadian population. A "get acquainted" period was observed in each province, featuring extensive educational campaigns with minimal enforcement. A gradual shift in public attitudes toward safety belts has been noted. Agencies promoting safety belt legislation over the years are the New Brunswick Safety Council (sponsoring a high school seminar on safety); the Conservative government of Premier Lougheed (press release on needless highway fatalities); the Edmonton Journal (editorial); and the Medical Assoc., the Motor Assoc., and the Safety Council of Alberta. A growth in seat belt use was noted in New Brunswick from 29% (Mar 1977) to 33% before legislation took effect, to 72% after legislation was implemented (Nov 1977-Mar 1978). In Dec 1978, overall compliance was estimated at 80%. Elements in the success of the program included a low-key educational advertising campaign, an information center, and a speakers bureau. Another factor was a crash simulator, the "Seat-Belt Convincer," which demonstrated the effects of a 6 mph crash. A 1978 Ontario government study projected a 21.6% decrease in hospital in-patient care, a 14.7% decrease in emergency outpatients, a 15.3% decrease in therapy treatment, and a 16.2% decrease in medical fees as a result of increased seat belt use. The average cost of medical treatment, broken down by seat belt usage in vehicles involved in accidents, was $228 where seat belts were installed and used, and $445 where seat belts were not installed. (The above figures were somewhat obscured by simultaneous reduction in speed limits in British Columbia and Ontario.) A greater interest has been noted in the use of car seats for babies, in spite of the high cost, due in part to rigid government standards. A car seat made in Australia for children between three and ten was promoted so successfully that local production in Canada and the U.S. is being arranged.

OPTIMIZATION OF DIESEL COMBUSTION RESEARCH

Some philosophical guidelines are presented on the objectives of engineering research and the mental processes of research are outlined: observation of phenomena, building of the physical model, and quantitative or mathematical description and validation of the model. The combustion process is discussed as a link between design and performance, including the following aspects of engine performance: fuel injection characteristics; power and cycle efficiency (peak cylinder pressure and heat release); emissions (nitric oxide, hydrocarbons, carbon monoxide, and particulates, control of white or blue smoke); mechanical aspects of noise, engine stressing and durability; cold starting; and fuel variation.

SHARP INCREASE IN DEATHS, NHTSA ADMINISTRATOR SAYS

Administrator Claybrook stated that the number of traffic fatalities is increasing faster than the number of registered vehicles, miles travelled, drivers licensed, and the U.S. population. The statement, which was excerpted and paraphrased, was made when four reports were released, including a 1975-1978 study of trends in the Fatal Accident Reporting System, which identifies the types of vehicles primarily involved in the increase in traffic fatalities. Remedies suggested include motorcycle safety, improved safety features in vans and in light and heavy trucks, and enforcement of the 55 mph national speed limit, especially in the western-southwestern states. Other reports released were preliminary findings from the National Crash Severity Study (NCSS) which identifies the type of injury, type of crash, vehicle speed, and other factors; the Five Year Plan for Vehicle Rulemaking; and a progress report that discusses what the industry is doing to meet Federal requirements for automatic belts and air bags, as well as agency programs to increase safety belt use. The NCSS file indicates that people involved in serious accidents use safety belts 8.4% of the time, a usage rate 40% lower than that of the general driving population. The NCSS file also shows that nearly a third of automobile accident fatalities occur when occupants are ejected from the car, especially in rollover and side impact collisions, and that over 90% of the serious injuries and fatalities in side crashes occur when the occupant compartment is damaged. Priority areas in the Five Year Plan include automatic belts or air bags, reducing pedestrian fatalities, extending motor vehicle standards to cover trucks and vans, improving braking requirements for all vehicles, and motorcycle safety. Heavy truck safety improvements will include rear underride protection, and improvements in fields of view, interior noise level, fuel system integrity, and ride quality.

EVALUATION OF PROGRAMS DESIGNED TO INCREASE THE PROTECTION OF INFANTS IN CARS

A group of postpartum women participated in each of three in-hospital education programs designed to increase the crash protection of infants in cars. One program distributed literature and made infant carriers readily accessible and convenient to purchase; another program provided literature and a personal discussion, as well as making infant carriers easy to purchase; the third program provided literature and offered a free carrier. The programs increased the use of infant carriers but had little or no effect on use of infant carriers fastened by a seat belt to provide crash protection. Among the methods suggested for increasing proper use of infant carriers are mandatory restraint laws and passive restraints. Increased protection for children, many of whom ride in the rear seat, could be achieved by increased crash padding of vehicle interiors.

AN UPDATE OF THE SURVEYS ON THE OPERATION OF NO-FAULT AUTO INSURANCE LAWS

A Dept. of Transportation (DOT) 1977 survey of premium rate changes from 1971 to 1977 in the 16 no-fault states and in representative states without no-fault laws indicated that premiums rose significantly in current dollars in virtually all cases, rural and urban, fault and no-fault; in constant dollars, most premiums decreased; and premiums in certain urban areas increased sharply, even after adjusting for inflation, in both fault and no-fault states. When adjusted for inflation, rates either held steady or dropped in Michigan, the state with a plan most resembling that proposed in the original DOT Auto Insurance Report. A Rutgers Law Review study evaluated the cost/benefit performances of the various state no-fault laws, and concluded that the no-fault benefits provided by add-on plans have been provided at significant additional cost. This type of no-fault plan is therefore unsuccessful in providing benefits at traditional fault-based insurance premium levels. In high benefit states (Colorado, New Jersey, New York, and Pennsylvania), total bodily injury premium levels increased by a mean of 15% and a median of 13%. In Michigan, an 11% decrease in total bodily injury premiums was noted, due to the state's practice of barring tort claims for pain and suffering. Examples are cited of the cost effectiveness of extraordinary expenses paid for by insurers in New Jersey. Advantages of no-fault insurance include greater benefits, more in keeping with actual losses, and more prompt payment, as well as compensation for losses and injury in one-car accidents, previously uncompensated. The 1977 DOT study concluded that state experience with no-fault automobile insurance would appear to confirm the basic soundness of the theory and the feasibility of the theory's implementation; that no-fault plans of sharply varying objectives and character are widely seen as successes; and that no problem has arisen in the implementation of no-fault for which there does not appear to be a readily available and feasible solution, given the political will to make the necessary change.

GETAWAY FLOW RATES FOR FREEWAY INCIDENT AND GEOMETRIC BOTTLENECKS

To aid in computational analysis for low-cost freeway incident management, values are presented of actual observed getaway flow rates from traffic incidents and geometric bottlenecks. Previously gathered data were used from three freeways in Los Angeles, Calif., and further data were gathered from the Washington, D.C. I-495 Beltway. Los Angeles data were collected from loop sensors imbedded in the freeway lanes and connected to a central computer. Washington D.C. incident data were collected by manual traffic counts from a one-direction three-lane section noted for frequent traffic incidents; bottleneck data were gathered at three locations. Analyses of both manual- and computer-detected freeway data showed that two distinct getaway flow rates exist: one for freeway incidents, the other for geometric bottlenecks. A reasonable value for the former rate is considered to be 1500 vehicles/lane/hour (v/l/h) although it varies from 1100 to 1900 v/l/h. The rate is slightly dependent upon incident type and number of vehicles involved, as well as traffic conditions (peak or off-peak). The geometric bottleneck getaway flow rate, involving the loss of more than one lane, is 2000 v/l/h, or approximately the freeway's capacity.

HAZARDOUS EFFECTS OF HIGHWAY FEATURES AND ROADSIDE OBJECTS--HIGHLIGHTS

Major findings are reported of research concerning the influence of the driver, vehicle, and roadside characteristics on the hazards of run-off-road (single-vehicle) accidents. Data were gathered on almost 8000 accidents in 1975-1976 by specially trained state police officers in Wyoming, South Dakota, Maine, Tennessee, Georgia, and California on noninterstate rural highways. Data are tabulated and discussed for accident frequencies for horizontal alignment by roadway type; accident frequency in relation to distance from previous horizontal curve, and from vertical curve; accident frequency and severity by vertical alignment; and severity of injury by horizontal alignment. Roadside factors were studied in terms of three basic off-road vehicle behaviors: rollover, nonroll impact, and no impact until a later road departure. Rollovers were more likely to occur on roads built on fill than on ditch cut roads; ditches, embankments, and culverts were overrepresented in nonroll impacts on ditch cut roads, with higher injury rate for deeper ditches. The most frequently struck objects in nonroll impacts were single trees, fences, wooden utility poles, embankments, ditches, guardrails, culverts, and small trees and brush. A large variation was found in angle of impact for guardrails (median of 9-11 degrees). Data are tabulated and discussed for vehicle behavior in striking guardrails and resultant driver injury, and driver injury by type of guardrail in primary impacts. An attempt was made to estimate the probable effect of roadside clear zones. Among miscellaneous safety features discussed, were curve delineation, center lines, improved light conditions, and curve warning signs, as well as increased shoulder width. Occupant ejection was considered the greatest determinant of injury; the injury rate was high for compounded or extended rollovers, and for striking nonyielding objects, injury rates increasing with increased speeds; injury rates were higher for frontal impacts in nonroll accidents. Other important injury factors were (in descending order) intoxication level, pole offset, passenger restraint use, horizontal curve length, predeparture maneuver, departure angle, driver condition, road condition, and distance from origin of tire marks to the departure point. These factors are divided equally among wholly driver determined, behavioral (interactions between driver and roadway), and roadway determined. The factors for which the driver is responsible are more statistically significant on injury than those under the control of the highway engineer.

THE APPLICATION OF VISIBILITY RESEARCH TO ROADS AND HIGHWAYS

Visibility and the related measurements of legibility and conspicuity are defined, and the improvement in highway visibility brought on by recent research is discussed, especially that sponsored by Federal Hwy. Administration programs. Laboratory studies have indicated that visual performance depends on the following factors: luminance adaptation level to which the eye is previously exposed, size and shape of the object to be seen, time of viewing, and contrast between the object and the background. Factors affecting driving steering control under adverse visibility conditions include illumination sources (natural or artificial); atmosphere characteristics (attenuating, scattering); driver vision, perception, and psychomotor skill; windshield properties; and road delineation. Among the experiments aimed at improving highway visibility are those with lighting (e.g. High Pressure Sodium vs. Mercury Lamp systems), both level and location, and pavement marking systems (paint color). Much of the research on sign visibility concerns legibility. Future research areas include the interaction of conspicuity and legibility of signs, interactive effects between methods used to enhance visibility, driver control loss brought on by poor visibility, and relationship of visual conditions along the highway and "highway effectiveness" measures.

DIGITAL DATA COMMUNICATION FEATURES IN PUBLIC TRANSIT SYSTEMS: TECHNOLOGY ASSESSMENT. FINAL TASK REPORT

A survey was conducted of the state of the art of automatic vehicle monitoring (AVM) systems and their use in public transit, taxi, and police operations. The systems identified are applicable to improving operational efficiency and quality of service. The various system elements related to AVM systems were reviewed, including vehicle location, identification and monitoring, computer scheduling, computer dispatch, silent alarms, security alarms, mechanical alarms, on-board readout, real-time display, passenger counting, management reporting, and digital data hardware. It was concluded that electronic vehicle monitoring increases service and efficiency in transportation systems; that some direct cost savings may be achieved in some communities; that AVM systems increase passenger safety; that data collection and retrieval capability provides information vital to increased operational efficiency; that an adequate supply of tested hardware components is available but increased costs for software offset reduced cost of electronic hardware; and that careful planning and personnel training are essential prior to system implementation. An in-depth study and demonstration program are recommended to develop a set of guide lines and/ or criteria for determining the need of Digital Data Communication systems under varying levels of transit demand and system characteristics, in order to establish the ranges of various parameters for assessing the cost/effectiveness of AVM systems. It is recommended that before selecting any particular AVM configuration, key personnel visit a location with a recently implemented system, for first hand observation and discussion of possible problems. Appended is a description of the E-Systems Mobile Digital Terminal 800.

AN INFORMAL STUDY OF TRANSIT BUS TIRE PROCUREMENT AND RECYCLING IN MICHIGAN

An analysis of tire procurement practices indicates that significant annual operating cost savings appear possible for four Michigan public transit authorities if they switch from leasing to purchasing tires. Further in-depth analyses of bus tire leasing costs appear to be warranted. An immediate switch from tire leasing to purchasing would require the purchase of all tires currently on buses and in spare inventory. Such a purchase could cause cash flow problems in Michigan public transit authorities' operating budgets. Outside funding from state or Federal sources for initial tire purchases could facilitate the changeover from leasing to purchasing. Rigorous tire inspection and maintenance (I/M) programs are necessary to maximize tire tread and carcass life; I/M provisions in tire lease contracts may contribute to extended life. Significant annual tire use cost savings appear possible through maximizing the use of recapped tires on bus traction axles. A detailed evaluation of the safety and performance experience of those Michigan public transit authorities currently using recapped tires would be helpful in providing data for the various transit authorities, some of which oppose the use of recapped tires for safety and operating reasons. Recapping of worn bus tires is the most cost-effective and energy-efficient means of recycling bus tires. Other recycling technologies include use as boiler fuel; chemical or pyrolytic decomposition as a source of rubber for new tires, or as a source of petroleum fuels and high BTU gas; use as a component of paving asphalt; and use in breakwaters or artificial reefs.

THE POTENTIAL FOR USE OF ALTERNATIVE FUELS IN MICHIGAN'S PUBLIC TRANSIT SYSTEMS. FINAL TASK REPORT

The availability of various alternative fuels (hydrogen (liquid and gaseous), alcohols (methanol, ethanol, and blends), broadcut and/or synthetic fuels, gasoline/alcohol blends) for public transit vehicles is examined, and funding opportunities for demonstration grants are discussed. The only alternative fuels that appear to be likely candidates for a demonstration grant in the near term are alcohol and synthetic fuels. The only likely supporter of a demonstration project is the Dept. of Energy, Div. of Transportation Energy Conservation, which has tentative plans for supporting some demonstration programs of alcohol/gasoline blends in the near future. It is recommended that there be a plan for a public transit demonstration project using alcohol in Michigan. The preferred alcohol would be methanol. Recommendations concerning such a project are provided, including construction and operation of a methanol pilot plant using forest product biomass and solid waste.

ANALYSIS OF THE NEISS [NATIONAL ELECTRONIC INJURY SURVEILLANCE SYSTEM] DATA FOR BICYCLE-ASSOCIATED ACCIDENTS. FINAL REPORT

Analysis of the 1976 and 1977 NEISS (National Electronic Injury Surveillance System) data on bicycle accidents has revealed little change in general patterns since 1975. The most evident feature is the large seasonal effect, while a small (not statistically significant) monthly increase in accidents is also noted, as is a slight shift to older ages for persons involved in bicycle-associated accidents. Although only about 3% of bicycle accidents investigated in depth occurred at night (midnight to 7 AM), these accidents were more likely to involve motor vehicles. These nighttime accidents resulted in more serious injuries than did most of the accidents investigated in depth. While bicycle use at night seems to be rare, bicycles ridden at night should have adequate illumination, and bicyclists should take extra precautions, since motorists do not expect to encounter bicyclists at night. A standard summary, developed earlier, is provided for bicycle-associated accidents reported through NEISS for the 1975-1976 period, as well as analyses of data from selected in-depth investigations.

AN AGE ANALYSIS OF TRAFFIC ACCIDENTS AND OFFENCES

Each category of traffic offense has been analyzed to determine the frequency of offenses per 1000 South Australian drivers in each five-year age bracket from 16-20 to 91-95 from Jul 1971 to Jul 1975. Data for this period have been analyzed relating to the age distribution of road users killed or injured in accidents, and the involvement in or responsibility for accidents according to age and road-user class. The one conclusion drawn from the analysis is that driving skill declines with age. The implication is that unless older drivers adjust their driving to account for their reduced skills, they are placing themselves and others at increasing risk. The need for retesting of older drivers has already been recognized in South Australia. Any driver over the age of 70 has to undergo a practical test before a new license is issued, the license being issued for a year instead of for three-years. An eyesight test is also introduced for drivers of 75 years of age. This system of retesting is a valuable basic appraisal of driving skill; the question remains whether more specialized forms of testing are necessary to identify a decline in specific skills.

PROCEDURES USED TO GENERATE INPUT DATA SETS FOR THE ARTICULATED TOTAL BODY MODEL FROM ANTHROPOMETRIC DATA

A general background is provided for techniques developed to generate input data sets for the ATB (Articulated Total Body) Model program from anthropometric data. The ATB Model was developed from the 3-D Crash Victim Simulator Model under the sponsorship of the Aerospace Medical Res. Labs. specifically for application to aerospace-type problems. The program simulates the dynamics of body motion using a unique method that has been shown to be equivalent to the Lagrange method. Motion picture films of the dynamics can be produced through the use of plot packages supplied with the simulation program. Techniques are described which were developed to generate body segment inertial data, to estimate joint locations and segment contact ellipsoids, and to define body and joint axes orientation. The state of the art of implementing these techniques is mentioned. Anthropometric data required for each of the body segments are appended, as well as expressions for the inertial properties of a simply-transected elliptical cylinder and of a simply-transected elliptical semicylinder with the surface curve removed.

FATAL MOTOR VEHICLE ACCIDENTS INVOLVING AUSTRALIAN CHILDREN

A comparative study is presented of child motor vehicle accident fatalities for the Australian states. The Australian traffic accident fatality rate for children (0-14 year age group) is 10.33 per 100,000 population at risk, a very high rate for the Western world. Age (0-4, 5-9, 10-14, and 15-and-over age groups) and sex-specific rates by states are tabulated. Fatality data are also compiled for two specific types of fatal traffic accidents involving children, run-down (pedestrian) and inter-vehicle accidents. Preventive strategies selectively directed towards these types of accidents are indicated. Further enforcement of seat belt legislation for children might be particularly effective in Tasmania and Queensland where there are high inter-vehicle fatality rates involving children. Comparative statistics for pedestrian fatalities show quite different patterns from those for vehicle occupants. Surprisingly, pedestrian fatality rates do not appear to be related to population density. Figures from Tansmania and Western Australia are high, and those from Victoria low. The higher figures for the less densely populated states may be mainly the result of an inverse relationship between vehicle speed and population density. The ineffectiveness of traditional safety campaigns to alter age-specific behavior to reduce pedestrian accidents is cited. More rigid control of vehicle speeds and improvement of visibility in dangerous sites are recommended. It is emphasized that no state should accept a child fatality rate greater than 3.0 per 100,000 population at risk for pedestrian or inter-vehicle accidents. This figure is now exceeded by five states for the former, and four states for the latter accident types.

FOCUS ON FACILITIES. SOME CURRENT THINKING ON "WHERE WE ARE" AND "WHERE ARE WE GOING?" [BICYCLING]

Telephone interviews were conducted with ten experienced bicycle facilities people concerning present bicycle planning directions. The persons interviewed offered a wide range of opinion based on involvement in government, academia, industry, and interest groups. An element of geographic bias was evident, as most participants came from coastal locations, with the Washington, D.C. and Portland-Eugene areas well-represented. The respondents' views are summarized. The discussions revolved about open-ended questions covering the following areas: the recent shift from bikeways as solution to an emphasis on education, and possible future trends; the optimum area for improving facilities in the broadest sense; statement of a case for facilities; role of facilities in increasing bicycle awareness; facilities that have worked; and further thoughts on facilities. Among the facilities discussed were operating space for bicyclists on arterial streets, better lighting, separate bikeways, lockers and showers.

COLLISIONS WITH UTILITY POLES

A detailed investigation of utility pole collisions is described, with particular emphasis on the engineering aspects of the accident sequence. Detailed measurements of site characteristics were made for 879 pole collisions resulting in vehicle disablement which occurred in the Melbourne metropolitan area (Victoria, Australia), and for a control group of 793 randomly-selected pole sites. These data led to the construction of an accident predictor model for estimating the annual number of accidents at a pole site from simple site measurements. It was determined that site characteristics associated with 50% of pole accidents on major roads, and 75% of accidents on minor roads, are associated with only 10% of the total pole population for these road classes. From accident records and other data, it was estimated that pole collisions result in 45 fatalities and 785 injured persons annually in Melbourne. Data from the accident-involved vehicles, compared with those from a control group of 627 randomly-selected vehicles, indicated that tire tread depths below 3 mm result in a progressive increase in accident involvement, as do deviations from specified tire inflation pressures and pavement skid resistance below 50. A strong correlation was found between injury severity and occupant compartment intrusion. Although side impacts are generally the most severe, the great majority of injuries result from frontal collisions because of their greater frequency. It was determined that when loss of societal welfare is measured in terms of current resource consumption and lost production, pole accidents in Melbourne cost at least $23 million annually. Benefit-cost analyses for various technical means of reducing accident occurrence or severity (breakaway or wrap-around luminaire supports, underground cables, offset poles) demonstrate the need for immediate remedial action.

HIGHWAY STATISTICS 1977

This compilation tabulates 1977 analyzed statistics on U.S. highway transportation covering the following areas of general interest: motor fuel, motor vehicles, driver licensing, highway-user taxation, state highway finance, highway mileage, and Federal aid for highways. Also presented are 1976 highway finance data for municipalities, counties, townships, and other units of local government. A listing of the data is given in the table of contents, and a brief description provided in the text accompanying each section. A brief section provides statistics for American Samoa, Guam, and the Commonwealth of Puerto Rico. A directory of additional data sources is provided, including suggestions for locating and obtaining transportation related statistics.

GRAPHITE-REINFORCED-PLASTIC PASSENGER CAR FRAME

A chassis frame, for a 1979 Ford LTD experimental vehicle, was designed and fabricated in graphite fiber-reinforced plastic (GrFRP). Prototype composite molding techniques were employed to form the closed frame sections required for strength and stiffness. Weight savings were realized because of both component integration and material substitution. Compared with its steel counterpart, the GrRFP frame affords a 79 lb (27.7%) weight reduction while providing a 33% increase in torsional stiffness and a 16% increase in bending stiffness. The frame passed laboratory suspension and steering load tests and has been incorporated in the experimental vehicle, but has not yet been vehicle tested.

DESIGN AND FABRICATION OF AUTOMOTIVE COMPONENTS IN GRAPHITE FIBER REINFORCED COMPOSITES

The design and fabrication of components of the 1979 Ford LTD experimental vehicle using graphite fiber-reinforced plastic (GrFRP), a material offering weight reduction (through material substitution, design changes, and part integration), are described in two parts. The design, finite-element analysis, and fabrication of the GrFRP for the concept vehicle body are described in Pt. 1. For the body-in-white, 104 steel parts, weighing 423 lb, were replaced by 41 GrFRP parts, weighing 160 lb, for a 62% weight reduction. The floor and body side panels represent some of the largest and most complex GrFRP automotive parts produced to date. The methodology and analysis used in developing the graphite composite lay-up design of the front end for the concept vehicle are outlined in Pt. 2. This assembly of GrFRP components weighs 30 lb, compared with 95 lb for the steel counterparts, and represents a 68% weight reduction.

TRAFFIC SAFETY EDUCATION. A GUIDE TO PREVENTING HIGHWAY DEATHS

Educational and medical countermeasures to prevent highway deaths and injuries, and postcrash rehabilitative services are addressed. As driver and traffic safety education programs for the novice are essential, it seems important to have periodic refresher courses, especially for those who have not driven for awhile. A medical exam might prove helpful to identify physical or mental deficiencies which could restrict an applicant's ability to drive safely. The practicing physician should become more cognizant of the need for critical evaluation of a driver's psychological and physical health; possible safety problems should be referred to the state medical advisory board for a decision. Great efforts to educate members of the various medical professions and the public are being made through such organizations as the American Medical Assoc., the American Acad. of Orthopedic Surgeons, and the International Assoc. for Accident and Traffic Medicine. Emergency medical services personnel are involved in detecting and reporting traffic accidents, rendering emergency care, and transporting the injured to hospitals. Rehabilitation programs for the physically disabled after an accident can provide job opportunities and enable these individuals to once again become productive citizens. The use of driving simulators in medical rehabilitation facilities is recommended. It remains to be determined which persons are unsafe drivers, due to the complex interaction of such factors as age, chronic disease, and prescription drug use, as well as non-medical factors.

GASOHOL TEST PROGRAM

A test program evaluated the effect of gasohol on emissions (evaporative and exhaust) when used as an automotive fuel. Gasohol fuels increased evaporative HC (hydrocarbon) emissions an average of 49% to 62% on 11 vehicles tested (4 three-way systems and 7 oxidation catalyst systems). Two mixed gasohol fuels (gasoline mixed with 10% ethanol) decreased exhaust HC by about 9% on all vehicles. A blended gasohol fuel (gasoline blended with 10% ethanol for correct volatility) increased exhaust HC by an average of 24% on all vehicles. Total HC for 3.3 trips/day increased 11% to 32% with gasohol fuels. Evaporative emissions contained about 0.6 g ethanol and 3.3 g to 5.4 g HC (as $CH_{1.85}$) with gasohol fuels. Carbon monoxide emissions decreased 20% to 34% with gasohol fuels, and nitrogen oxides emissions increased 6% to 11%. Fuel economy (by carbon balance) decreased 1% to 5% with gasohol fuels. Driveability complaints increased with gasohol fuels. Three-way catalyst systems were not appreciably different from oxidation catalyst systems in exhaust and evaporative emission sensitivity to gasohol fuels. It is not known if a gasoline fuel containing 10% ethanol can be commercially blended to match distillation characteristics of gasoline fuel containing no ethanol, nor is it known if a "blended" gasohol with volatility characteristics similar to a gasoline would give driveability or evaporative emission levels similar to the gasoline. Appended are a listing of the test procedure, typical fuel inspection data, vehicle specification sheets, and test result tables.

TARGET: HIGHWAY RISKS. 2. THE GOVERNMENT REGULATORS

In view of the available scientific knowledge, the question is asked why the possible 80% elimination of the present automobile fatalities in the U.S., is not realized. The answer is framed in terms of two models of hazard and hazard control (one developed at Clark Univ., the other by Dr. w. Haddon of the Insurance Inst. for Hwy. Safety). Each model envisions stages of hazard development over time, starting with early and fundamental "causes", continuing through intermediate stages, and leading finally to consequences. The models define the structure of hazard causality and the range of control actions available to managers. When the history of auto hazard management in the U.S. is examined in the context of these models, it is concluded that driving risks could be reduced as much as five-fold. The political crisis of the early 1960's (increase in death rate per vehicle mile for the first time in decades), which led to major Federal intervention in 1966, was as much a crisis of increased driving and of demographics as a crisis of inadequate safety management. Actual improvements in safety since 1966 have been far less than those theoretically achievable, the failures being political failures. Failure can be attributed not only to the weakness of the Federal bureaucracy in the face of industry pressure, the direct interference of the President, and an indifferent public; it also is rooted in the persistence of the preconceptions that dominated pre-1966 hazard management philosophy. Since 1966, much more emphasis has been placed on the later stages of hazard management (i.e. crash and post-crash phases). The 1966 changes (brought about by the Highway Safety Act, and the National Traffic and Motor Vehicle Safety Act), may simply need more time to be absorbed. The final prognosis, however, is not a hopeful one; much improvement in hazard management will, as in the past, be vitiated by the risks created by increased driving and may, because of the introduction of smaller, less crashworthy cars, even exceed present loss projections.

THE USE OF ALTERNATIVE FUELS IN HIGHWAY VEHICLES--THE RELEVANCE OF U.S. ENERGY FLOWS

A new energy model for the U.S. has been completed and tested which uses more recent fuel and energy data than the 1976 Gulf Oil Co./Stanford Res. Inst. data base and which calculates transportation energy flows and pricing through the year 2020. This equilibirum or "balance of forces" type of model calculates a slow rise in prices for transportation fuels over the time period. Two import oil price situations, per barrel prices of $12.75 and $15.50, have been modeled. The model calculated that the higher price would result in the earlier introduction of synthetic fuels. It also showed that the alternative fuels methanol, electricity, and broadcut fuel could be economically competitive and thus enter the transportation market, while hydrogen could not.

MARIHUANA AND DRIVING HAZARDS

Evidence is drawn from 22 scientifically valid reports published in international journals showing the detrimental effect of marijuana use on traffic safety. Recent research indicates that cannabis (marijuana) use is positively associated with the traffic accident toll. In controlled laboratory studies, marijuana has also been shown to adversely affect perception skills, coordination, braking time and other motor skills, mood, judgment, etc. Driving studies (under controlled and normal traffic conditions), indicate that marijuana adversely affects driving safety. Appended are a summary of topics covered by the 1975 International Symposium on Drugs and Driving, held in Bloomington, Ind. and sponsored by the National Hwy. Traffic Safety Administration; and a list of literature reviews and bibliographies on the subject of drugs and driving.

A BICYCLE ACTIVIST LOOKS AT FACILITIES

In a discussion of bicycle facilities development in the U.S. from its first stage (construction of bikeways during the modern bike boom), through its second stage (experienced bicyclists wanting widened highways for bicycle and automobile traffic and bicycle parking) to the present, the third stage involves putting the improved facilities information to prudent use. The disparity in point of view between bicyclists and the facilities provisioners is seen as the prominent characteristic of this third stage. Access to roads, road engineering to accommodate bicycles, parking and storage, and interface with public transport are individually addressed as the four essential bicyclists needs. Supplemental comments are made in support of the use of recreational department budgets for creation of recreational bicycling facilities (i.e. bikepaths in parks), and the appointment of active bicyclists to facilities provision positions or any other aspect of bicycle programming.

BICYCLE FACILITY STANDARDS. DESIGNING FOR TOMORROW WITH OBSOLETE INFORMATION

A hypothetical bicycle facility project failure is described which points to the need for an educational program to overcome many problems faced by bicycle facility engineers and planners. Educational requirements to update planners' and engineers' thinking are addressed: the need to realize that bicyclists are not a homogeneous group; the need to include bicycle transportation as part of planning and engineering curricula; and the need to keep informed of the latest bicycle transportation planning and design developments. The American Assoc. of State Hwy. and Transportation Officials' (AASHTO) "Guide for Bicycle Routes" (1974) is described, including an outline of some of its outdated aspects (no discussion of different types of bicycle user groups, some design alternatives found to be undesirable). The Federal Hwy. Administration's (FHWA) great contributions, since 1974, to the knowledge of planning, design, and construction of bicycle facilities are acknowledged. Reliance on the AASHTO Guide prevails because newer information and research results are seldom circulated to persons directly responsible for planning, design, and construction. The passage of the 1978 Highway Act is expected to change this situation. The FHWA is to develop a design guide including criteria for bicycle facilities which will provide adequate roadway space and convenient bicycle travel, secure bicycle parking at major destinations, a good riding environment in residential areas, and independent bikeways. The most current state-of-the-art document, the California Dept. of Transportation's "Planning and Design Criteria for Bikeways in California" is recommended.

ROAD TEXTURE INDUCED EXTERNAL TIRE NOISE. EMPIRICAL FREQUENCY RESPONSE FUNCTION FOR TIRES

Based on three earlier tire/road noise studies (cooperative projects between IFM Akustikbyran A.B., and Statens Vag- och Trafikinstitut (VTT), and sponsored by the National Swedish Board for Technical Devel.), analyses are made of correlations between exterior tire noise and road roughness (texture). Measured tire noise frequency spectra for a passenger car tire and a truck tire rolling on three road surfaces were analyzed, as well as frequency spectra of the longitudinal surface profile curves recorded by a profilometer for the corresponding road surfaces. A distinct correlation is found between these differential spectra for a radial passenger car tire with "summer" tread rolling on a rough-textured road, indicating that texture-induced tire vibrations are the dominating noise generation mechanism. Frequency response calculations (approximations) indicate that the tested passenger car is sensitive to road texture in the region from 125 Hz to 1000 Hz, corresponding to road irregularity wavelengths of 160 mm to 20 mm. The truck tire appears to be about as sensitive to road texture as the passenger car tire, if compensations are made for contact area differences. In theory, clearly detecting a frequency shift due to speed for texture-induced noise is possible only for a periodically grooved pavement and a smooth-patterned tire. Results suggest that a tire, with respect to texture-induced noise, can be considered as a filter; the filter model may be included in a more complex model explaining all tire noise generating mechanisms.

FIT SHOCK ABSORBERS TO YOUR CUSTOMERS NEEDS. A GUIDE TO SHOCK SELECTION AND INSTALLATION

Information on shock absorbers, obtained from Monroe engineers, is presented for the undercar service specialist. The function of a shock absorber is explained, and its structure illustrated. Diagnostic inspection procedures are outlined for determining whether shock absorbers need replacement. Information is given on how to select the type of unit (using the Monroe line of shock absorbers as examples) best suited to the needs and requirements of an individual driver and a particular vehicle. Installation advice is given, emphasizing the importance of following the instructions enclosed in the shock absorber carton and pointing out shock clearance problems when mounting heavy-duty shocks on downsized cars, particularly American makes cited (illustrations show areas where grinding or bending needs to be done). Some general installation tips are outlined. Special mention is made of load-leveling shock absorbers which, unlike other types, carry weight.

FUEL-CRISIS FUN. FIVE SPORT COUPES THAT OFFER ALL THE FUN YOU CAN STAND AT 20 MPG

A comparision was made of five sports coupe models which were selected on the basis of offering a minimum of 20 mpg in the city cycle and of acceptability to the sports coupe enthusiast in handling, performance, technological sophistication, and style. The five choices of the "Car and Driver" (C/D) team were the Volkswagen Scirocco, Dodge Omni 024, Mazda 626, Mercury Capri, and Honda Prelude. The Scirocco, Omni, and Prelude have front-wheel drive, the Scirocco, Mazda, and Prelude have five-speed manual transmission, and each car is equipped (standard or optional) with a full complement of performance wheels, tires, and stripes. Vehicle specifications are tabulated: base and as-tested prices, engine, transmission, hp, torque, wheelbase, curb weight, suspension, steering, brakes, and tires. The C/D team of drivers evaluated the cars on a 500-mi trip over Michigan and Ohio Interstates and tortuous country roads in terms of fuel economy and driving enjoyment. Drivers changed cars at intervals and utilized a CB radio network. A performance comparison table provides data on acceleration, top speed, braking, maneuverability, interior sound level, and mpg. A photograph of each car is provided, as well as a summary of its advantages and disadvantages. The Omni was the overall mpg champ at 30, followed by the Scirocco and the Mazda tied at 28, the Prelude at 25, and the Capri at 20. All of the sports coupes were found "fun to drive".

AUTOMOTIVE ELECTRONIC SYSTEMS

Fourteen papers are compiled, designed to bridge the communications gap between automotive engineer and electrical engineer and to promote a better understanding of electronic systems using custom integrated circuits and/or microcomputers. Papers are presented on the following topics: microprocessors, custom integration, application of custom integrated system, and microcomputer system applications.

INTRODUCTION TO MICROPROCESSORS

The functions of the components of a microcomputer and their interactions are described. The microprocessor, clock, memory, and input/output section are defined and discussed. Definitions are given for microcomputer, microprocessor, single chip computer, custom integration, and minicomputer. The two types of primary memory (read/write and read only) are explained, including number systems and codes, and microcomputer software. The relationship of binary and hexadecimal numbers to machine language and assembly language programming is elucidated.

INTERFACING TO THE MICROPROCESSOR

The function of interfacing devices is explained. These devices, called busses (groups of signal wires with a common function), connect the memory and external devices to a microcomputer; the nature of the information transferred is described. A microprocessor is a single integrated circuit (IC) that implements the control unit and processor of a computer; most microprocessors communicate via three busses (address buss, data buss, control buss). Since it is not practical to extend the busses to devices external to the computer, an interface IC is used to route the proper information to the microprocessor at the correct time. These IC'S contain input ports, output registers, and flags. Both single-purpose and programmable interfacing IC'S are widely available. Memory mapped input/output hardware is very common in typical microcomputer applications, and both polling and interrupt techniques are frequently used.

HS-026 465

MICROPROCESSOR SELECTION AND SOFTWARE DESIGN

Some of the parameters involved in selecting a microprocessor for a particular application are listed and their interrelationships discussed. The most important parameters are application-dependent and include number of inputs, number of outputs, required throughput, type of interfaces, and the total number of systems to be produced. Another set of parameters is microprocessor-dependent and includes instruction set, throughput, and hardware and software support. Parameters related to in-house hardware and software expertise must also be taken into account.

HS-026 466

DESIGNING RELIABLE SOFTWARE FOR AUTOMOTIVE APPLICATIONS

Approaches are discussed for programmers to use in protecting their software against flaws in the hardware system due to hostile automotive environment. Failure modes considered are random occurrences of noise spikes (noise "hits") causing false inputs or changes in the state of various memory elements of the automotive microcomputer. Various techniques for writing "fail-safe software" for these microcomputers are discussed. These structured programming techniques help reduce the probability of executing (or increase the probability of detecting) a "tight loop" which results in a lock-up condition. Graceful recovery (i.e. setting the system back into correct operation), once a system fault has been detected, is considered. Filtering to desensitize programs to noise inputs is mentioned, as well as the use of a dead-man timer to detect lock-up. The general techniques are illustrated through the use of an Intel 8048.

CUSTOM MOS [METAL OXIDE SEMICONDUCTOR] FOR THE AUTOMOTIVE MARKET

The development of a custom MOS (metal oxide semiconductor) circuit is considered, with particular reference to the automotive market. Custom MOS, which may be a single chip or a multi-chip system, is a synergism between the end-product developer and the semiconductor technologist. The available production-tried processes are described for development of a custom circuit (P Channel MOS, N Channel MOS, and Complementary MOS). Cost, package constraints, input/output (I/O) considerations, complexity, and power are outlined as items to consider when partitioning (the key to a successful product). I/O voltage protection structures used in MOS design are considered. Custom MOS/LSI (large-scale integration) product development is traced from the identification of a need to customer acceptance (including a flow diagram). Some automotive applications for custom MOS are listed (e.g. speed control, engine control, accessory controllers, safety warnings).

STANDARDIZE OR CUSTOMIZE? WHY NOT DO BOTH [MICROCOMPUTERS]

The on-going event called the "microprocessor revolution" and its evolution toward total system integration or "system on silicon" are discussed. Integration of the computing system is considered, as well as of the controlling interfaces. The dilemma of using industry standard devices or of committing time and money to develop a custom device is addressed. MOS (metal oxide semiconductor) process technology advancements are allowing greater device densities on a silicon chip, which in turn are permitting increased functional integration. Microprocessors are giving way to microcomputers, which on a single chip contain mask programmed ROM (read only memory), RAM (random access memory), a timer, external interrupt hardware, on-board clock oscillator, and programmable input/output lines. Some microcomputers are expandable to include off-chip memory and peripherals. A new microcomputer has been designed to accomplish further levels of integration for unique control situations. The need to interface with the control environment and its impact on custom integration is the prime consideration for the architecture of the Motorola MC6805 single-chip microcomputer. The 6805 is designed to help bridge the gap of design time and investment capital that exists between standard microprocessors and custom-designed controllers.

CUSTOM BIPOLAR INTEGRATED CIRCUITS FOR AUTOMOTIVE APPLICATION

An overview is provided to the automotive system manager for selecting and developing a custom bipolar integrated circuit (IC) to meet a system need. It is first necessary to determine the cost/effectiveness of customizing a system vs. using standard, off-the-shelf components, as well as to determine the extent of system integration desired, the type of interconnect needed, and the constraints of semiconductor packaging. Available lead time must be determined, and electrical, environmental, and mechanical specification limits defined. Number of sources, and parts interchangeability need to be addressed. Once the decision has been made to customize, the next desired function must be achieved within an acceptable schedule. At this stage, the system manager shares some control over the success of his program with the semiconductor supplier. The basic development cycle consists of the following major steps: selection of semiconductor supplier, contract definition and negotiation, circuit design, breadboard, design review, circuit layout, layout review, mask making, pilot wafer run, device characterization, specification review, life test, and release to production. Reaching a successful conclusion requires considerable positive interaction between system manager and semiconductor supplier.

AUTOMOTIVE IC'S [INTEGRATED CIRCUITS]--THEY WORK

The application of microelectronic components to automotive electronic systems now appears capable of reaching the proportions predicted in the early 1970's, but the challenge is to achieve very high reliability under the severe conditions of the automotive environment. The continued growth of automotive applications may depend on resolution of reliability problems without significant add cost. State-of-the-art integrated circuits (IC'S) will work in automotive electronic products, but making them work will require substantial commitment by both the semiconductor and automotive industries. Individual part stress testing must be continued to remove potentially defective devices. Reliability test requirements should be standardized to the greatest extent possible, for straightforward comparative analysis and minimum test cost. Automotive product organizations must gather the expertise to provide interactive involvement in failure mode identification, testing, and environmental effects analysis.

CUSTOM CMOS [COMPLEMENTARY METAL OXIDE SEMICONDUCTOR] APPROACH TO AUTOMOTIVE INSTRUMENTATION

Custom CMOS (complementary metal oxide semiconductor) approaches to most measurement and warning signal needs of the automobile are discussed. Included are considerations for selection of a technology, possible circuit approaches for system design needs, characteristics of the technologies, and variations to be expected with environmental changes. Device and building block characteristics of the technologies are considered, along with their variations. Environmental protection such as input protection techniques for electrical transients and temperature excursion are discussed. Original design custom circuits are described for monitoring nine functions in a car (high/low voltage, engine hot, low coolant, headlights on, seat belt, low fuel, key minder, door ajar, bulb check), and a bi-torque tachometer driver. Diagrams of the circuits accompany the text.

FORD SPEED CONTROL UTILIZES I2L TECHNOLOGY

The new 1979 Ford speed control system features a custom hybrid (analog and digital) LSI (large-scale integration) circuit, fabricated using I2L technology, in place of the all discrete component electronics formerly used, and incorporating a "resume" feature not previously offered. The system, which is offered for the first time for manual transmissions, was independently designed by multiple vendors from functional block diagrams, which included definition of all external components and characterization of all inputs and outputs. The new system is a smaller, lighter, and potentially more reliable control module than its predecessor. Manufacturability has been enhanced by the reduction in parts count and assembly procedures due to the integration of processing and memory functions into the integrated circuit.

APPLICATION OF ELECTRONIC SYSTEMS AT FORD

Ford Motor Co.'s activities are reviewed in the application of electronic systems both in the vehicle and in manufacturing. Some advanced concepts for automotive controls are discussed, including an explanation of how the speed and power of the chip computer are utilized for real-time integrated controls and how loops are closed for adaptive controls. The question of the ability of the service industry to handle these new controls is addressed, with emphasis on the computer's ability to diagnose its own control systems. The rapidly spreading use of microprocessors in automotive manufacturing plants is described, and resulting opportunities in mass production functional control indicated.

A SINGLE CHIP MICROCOMPUTER WITH SYSTEM FEATURES

A new microcomputer family, the S2000, has been designed to minimize system parts count by integrating system requirements "on chip", and has been specialized for various system requirements. The family approach allows the system features to be enhanced when desired by moving up the line while maintaining compatibility in software and general familiarity from the system designer's point of view. The family characteristics go from the low end S2000 (1K byte ROM (read only memory) and 64 nibble RAM (random access memory) to the S2400A with 4K byte of ROM, 128 nibbles of RAM, D/A (digital/analog) and A/D converter, high voltage outputs, etc. For special applications, the S2200C is identical to the S2200 except designed in CMOS (complementary metal oxide semiconductor) for low-power applications. The S2000 family is designed with a system solution in mind. Special instructions allow single byte manipulation of typical automobile control problems. Appended is a S2000/2150 and S2200/2400 instruction set summary of program control instructions.

TECHNIQUES FOR APPLYING SINGLE CHIP MICROCOMPUTERS TO AUTOMOTIVE PROBLEMS

The application of single-chip microcomputers to automotive control systems is discussed, particularly in terms of cooperative planning by the designer, the manufacturer, and the user. The advantages of a microcomputer are discussed (e.g. small size, customized logic functions, low cost, high-volume standard products), emphasizing that success in application requires careful and involved management decisions. Selection of a microcomputer by the automotive system management is discussed, the most important factor being the careful definition of the function of the end product. The need for a close association between hardware and software design is discussed. The single-chip microcomputer is discussed in terms of tolerance in the automotive environment. Testing of the microcomputer via an incoming inspection of the components and a functional test of the unit operating in the end system is described. There needs to be a close relationship between customer and supplier in terms of milestones in the manufacturing and delivery cycle so that delivery and projected need can be coordinated; a cycle typical of the industry is described. A glossary of "buzz" words used to describe single-chip microcomputers is included.

MICROCOMPUTER--SIMPLIFYING SOPHISTICATION

Following a general description of the manufacture of microprocessors, including quality control points, testing criteria, and cycle times, the Mostek MK3870 family of microcomputers is discussed to illustrate the sophistication of state-of-the-art MOS/LSI (metal oxide semiconductor/large-scale integration) and automotive applications of this technology. The devices in the 3870 family are complete 8-bit microprocessor systems on a single MOS integrated circuit. All family members execute the F8 instruction set of more than 70 commands. ION-implanted N-channel silicon-gate MOS with advanced circuit design gives the MK3870 the excellent reproducability, reliability, and low component cost vital to a wide range of control and logic applications. The concept of In-Socket Expandability provides the designer with the ability to enhance or expand a system into which the 3870 is designed merely by replacing the 3870 with another member of the family (2876, 3872, 3873). The 3870 can be applied in engine control, keyboard displays, and serial link distributed processing networks.

CONCEPTION OF ESTABLISHING EDUCATIONAL INSTITUTIONS TO TRAIN TRAFFIC SPECIALISTS. PROJECT REPORT

The specialized training of personnel to teach traffic safety and the establishment and maintenance of a social system for that purpose in Japan are proposed. It is felt that the present education and training of traffic safety instructors are qualitatively and quantitatively inadequate. The establishment of a "Traffic University" is proposed which would offer an education comparable with that of a regular university. This university would train personnel to provide traffic safety guidance to youth from kindergarten through high school and up to the university level, as well as to the public in general. The institution would also provide training in driver education, as well as in traffic-related professions (e.g. traffic control officers (police department), automobile insurance investigators). Problems of traffic safety education in the present school curriculum are addressed, and a tentative scheme is presented for the "Traffic University", including curricula. The problem of "bosozoku", or hot rodder gangs is mentioned, as well as of high school motorcycle riders. Interim measures are proposed, including lecture meetings to prepare for national examinations, correspondence courses, and establishment of a preparatory institute, such as the International Assoc. of Traffic and Safety Sciences.

SYMPOSIUM "THE TRAFFIC DILEMMA." PROJECT REPORT

Key points made in panel discussions and subsequent open discussions at a symposium on "The Traffic Dilemma" are presented, as well as an overview of the subject. Aspects covered in the session on the psychological analysis of traffic included the pleasure of speed, the Japanese enthusiasm about mechanical things, separation and integration of people and vehicles, integration of vehicles and space, and problems involved in utilizing foreign-origin public transportation systems. In the second session, the concept of sociological dysfunction (unforeseen consequences of a more closely integrated society) in the development of transportation systems was addressed. The final session discussed the traffic dilemma in terms of the overuse of transportation, the loss of independence by service companies due to public control and support, overuse of space, conflicts due to transportation links between large and small areas, and expansion and improvement of roads resulting in increased traffic volume. Cultural and psychological differences were stressed in connection with all phases of the transportation problem.

THE IATSS [INTERNATIONAL ASSOCIATION OF TRAFFIC AND SAFETY SCIENCES] SYMPOSIUM ON TRAFFIC SCIENCE 1978: MOBILITY FOR MAN AND SOCIETY, PROJECT REPORT

The background and organization of the International Assoc. of Traffic and Safety Sciences Symposium on Traffic Science are described, and summaries are presented of the papers delivered in each of five sessions. The theme of the international symposium was "Mobility for Man and Society". It was realized that various transportation problems today cannot be resolved unless the concept of mobility is analyzed from a broad perspective including cultural and historical considerations. The five sessions were: Why Mobility?, Mobility and Human Behavior, Mobility Needs in the Society, Mobility Planning, and Mobility for a Better Environment. A round-table discussion concluded the symposium. A copy of the agenda is included.

FASHION AND TRANSPORTATION

The social psychology of human mobility is examined with reference to the automobile. The significance of the interaction of the concept of "fashion" and of human mobility in modern culture is discussed. A new approach to cultural studies is seen necessary, described as that of "mobile humanity". Communications, transportation, fashion, and "mobility space" are discussed as they apply to this approach. Fundamental trends in fashion (popular music, "outdoor-oriented culture") are examined as they relate to mobility space and the use of cars. Some insights are presented on the impact of industrialization and consequent social mobility on the traditional Japanese view of social strata as the most important basis in human association, as well as the impact of communications media and of rapid transportation.

GENERAL EVALUATION OF TRAFFIC ACCIDENT COUNTERMEASURES

In the 1970's, there has been a continuing decrease in the number of traffic accidents in Japan. The 718,080 accidents recorded for 1970 were down to 471,041 in 1976; the number of fatalities was reduced from 16,765 to 9,734. This decrease is encouraging from the perspective of an international comparison and for the long-term trend. Traffic accident figures for other countries indicate that the decrease will soon level off. On the whole, Japan's traffic safety countermeasure policies (Fundamental Law of Traffic Safety Countermeasures of 1970, First Traffic Safety Fundamental Plan of 1971-1975, Second Plan of 1976-1980) have heretofore met with quite a degree of success. Problems that remain include inadequate provision for "traffic orphans" (one or both parents lost in a traffic accident), inadequate ambulance and emergency services, and inappropriate pedestrian crosswalks and bridges. On a scale of 100, Japan's traffic accident countermeasure program ranks 70. For the future, it is essential to systematically rank traffic safety priorities, and to collect accurate traffic safety data. Countermeasure program evaluation methods are discussed, including comparisons of purpose, standards and results, comparison with other areas, cost and effect, and analysis of the contributions of individual countermeasures.

BASIC RESEARCH ON REAR-END COLLISIONS

Statistical data on traffic accidents which occurred on streets and highways throughout Osaka prefecture (Japan) from 1973 to 1975 and on the Hanshin Expressway (Osaka) from 1972 to 1976 have been analyzed in terms of rear-end collisions. Rear-end collisions on the roads in general were the second most frequent type of accident, exceeded only by vehicle-pedestrian accidents, and accounted for 1/4 of the accident total. More rear-end accidents occurred on trunk roads such as national highways, with increased occurrences at intersections. On the Hanshin Expressway, two-vehicle crashes accounted for 60% of the total accidents, with 78% of them being of the rear-end type. On the roads in general, the annual rear-end accident rate was found to be 55/100 million vehicle km; for the Hanshin Expressway, it was found to be 14/100 million vehicle km. A direct relationship was found between number of rear-end accidents and traffic volume. No clear relationship was found between number of rear-end accidents and road geometry. Countermeasures are outlined from the standpoint of human factors, traffic management, traffic safety facilities, and road engineering.

WHAT YOU SHOULD KNOW ABOUT AUXILIARY TANKS [RECREATIONAL VEHICLES]

Information is presented for the recreational vehicle owner on the selection and installation of auxiliary gasoline tanks. Auxiliary fuel tanks, their typical locations and gasoline safety cans are illustrated, and a list of tank manufacturers is provided. Some pointers are provided on tank quality as there are few regulations governing production and use. Any tank should be sturdy (heavy gauge metal), with internal baffles for restraining liquid movement in the tank. Reputable fuel tank manufacturers will readily supply all the details about their products, will demonstrate installation fittings, and will explain their testing procedures. Tank warranties are important. Reputable manufacturers conduct crash tests to verify that a tank designed for a specific location on a specific make, model, and year vehicle will withstand various crash conditions. Reputable firms do not mount a tank in a vehicle they have not tested, nor in an innovative location. The major criteria in mounting positions are protection, support, and anchoring (preferably to the frame). Compartment locations should obviously be vented and thoroughly isolated from the coach interior. Fuel emission standards specify that fumes from a fuel tank must not enter the atmosphere. Tanks must be designed so that they can not be filled to capacity and so that they have a vent through which fumes are carried through a filter into the carburetor. Tanks which contain unleaded fuel must also have a fill neck too small for a leaded gas pump nozzle. Safety considerations for using a spare gasoline can rather than a spare tank include use of a safety container (i.e. cannisters made with a special spring closure, a device for preventing sparks from igniting vapor, a vapor vent, a pouring spout, and an approved label), locating the can in a garage or shed well removed from heat or ignition sources, and storing only small quantities of gasoline.

ALCOHOL FUEL: THE GREAT CLEAR HOPE

The potential for alcohol fuels (methanol and ethanol, pure or as gasohol) in the U.S. is explored. Background information is given on these fuels in terms of source, production, current use, potential applications, and growing support for their use. The source, economics, commercialization, and safety and environmental implications of alcohol fuels as an alternative energy source are separately discussed. Places to contact or visit and publications to read regarding alcohol fuels, energy policies, technology, or do-it-yourself production (including special loans) are listed. Further discussion of gasohol is included in a separate article, "Washington Dateline," by Wayne Kennedy.

THINK SMALL: AUTOS VS. MOTORCYCLES [MOTORCYCLE CONSPICUITY]

About 60% of automobile/motorcycle accidents are considered to be the fault of the car driver, the main cause being the driver's inability to see the motorcyclist (even in daylight hours). Motorcycles are difficult to see because of their relative smallness. Some of the blame for these accidents also lies with cyclists' faulty riding habits, such as riding to the far left or right of the lane, out of the scope of a rearview mirror and in the blind spot of the car in front. If a motorcyclist uses the center of the lane, oil and grease reduce his traction by as much as 60%, too high a price to pay for increased visibility. Riding at the edge of the lane makes the motorcycle difficlt to see for a car pulling out of an alley or a parking lot. Unsigned and unsignaled intersections create another situation of reduced visibility, especially where trees may hide the motorcycle from view. Dangerous antics by motorcyclists (e.g. riding down the center line between lanes of traffic, dodging slower-moving cars) are also a threat to all motorists. Recent legislation by most states requires motorcycle headlights and taillights to be on when the cycle is in operation, and some states require front and rear turn signals. Many motorcycle manufacturers are now installing large reflectors on the sides of motorcycles. Clothing and helmets are being designed in bright colors, often with strips of reflectorized tape. Motorcycle safety classes are offered by most motorcycle shops and by many police departments.

THERE'S A FIRE ENGINE IN MY TRUNK! [CLEARING THE ROAD FOR EMERGENCY VEHICLES]

Tips are provided for the motorist on how to react when an emergency vehicle is approaching. Comments by a California Highway Patrolman and a fireman from the Novato Fire Protection District (Calif.) are included. When a driver hears a siren from behind, he should look around before pulling over to the far right side of the road (as prescribed in the driver's manual). If a patrol car appears to a motorist's right, the motorist should slow down and remain where he is. If there is an open space on the motorist's left, the patrol car is directly behind, and the motorist cannot go to the right, the motorist should go straight ahead so that the emergency vehicle can move into the open space. The rule of moving to the far right applies whenever possible. If a patrol car is merely flashing the red light, a motorist need only stay out of the way. An approaching ambulance or fire engine with siren and flashing light, will move in response to the motorist's movements. Once a motorist has started to make a move, he should follow through. If a driver cannot locate the source of the sound of a siren, he should pull over to the right until a determination can be made. The patrolman and the fireman feel that motorists in general are cooperative and quick to comply in emergency situations.

LOUISIANA'S TRUCK PERMIT SYSTEM WINS PRAISE OF OFFICIALS, TRUCKERS, AND PUBLIC

Since the Truck Permit Office in Louisiana's Dept. of Transportation and Development began operations on 29 Jun 1977, it has been much easier and more convenient for truckers to obtain permits for overweight and oversized loads. The new operation has centralized issuance responsibility, that had previously rested with 11 different state police troops, in one office in Baton Rouge, allowing for more standardized procedures and improved availability of permits. Permits can now be obtained by any one of five methods: in person, by application through the mail, by charge account, by a prepaid permit system, or through the wire services. The main advantage of having a charge account is that it only takes 3 min. to activate a permit by telephone. The Truck Permit Office operates 14 hr/day during the week, and 7 hr on Saturday. All clerks are required to have a working knowledge of Louisiana weight laws to facilitate rapid processing of permit requests. Since clerks do not actually see or inspect a vehicle when they issue a permit, the information on the permit is checked against the vehicle and load by weight enforcement officers in the field. Vehicles with gross axle weights exceeding 212,000 lb may be subject to special restrictions, and applications must be submitted well in advance of the intended trip; loads in this category are granted permits only if there are no other means of movement than a public highway. The entire operating cost of both the Weight Enforcement Office and the Truck Permit Office is covered by truck permit fees. For FY 1978-1979, the Truck Permit Office will collect an estimated average of $420,000/mo.

AN EVALUATION OF OHIO'S RANDOM MOTOR VEHICLE INSPECTION PROGRAM

Most available evidence implies that the random motor vehicle inspection, as conducted by the Ohio Highway Patrol, has little potential for reducing the number of traffic accidents, compared to other safety measures. Vehicle defects are estimated to cause only 6% of all traffic accidents nationally; the Patrol estimates less than 3% of Ohio accidents are caused by such defects. Random inspection has no "inspection effect," if fewer than 20% of the vehicle population is inspected; the Patrol annually inspects around 10% of the registered vehicles in Ohio. Although no direct relation between inspection programs and accident rates has been established, states with periodic inspection generally have lower fatality rates. The Dept. of Transportation's list of 37 traffic safety measures does not include random inspection. Since roadside inspection is less effective than garage-based inspection in checking critical components (e.g. brakes, wheels, tires), the usefulness of the Patrol inspection procedure is questionable. The present Ohio program includes inadequate follow-up, and does not concentrate on high-risk older vehicles. Costs of Ohio's program are exceeding benefits. Because of inspection site locations, Ohio's program is not random. To improve the program, it is recommended that: the Highway Patrol locate inspection sites in urban areas, selectively inspecting older vehicles; increase inspection hours and follow-up; and improve inspection quality. Alternatively, it is recommended that the General Assembly eliminate the motor vehicle inspection program, implement a periodic inspection program, reallocate program funds to other highway safety measures, or support a greater or lesser number of inspection teams as funding permits.

ILLINOIS TRAFFIC SAFETY PROGRAMS. REPORT OF EVALUATION OR ASSESSMENT. CONCENTRATED TRAFFIC ENFORCEMENT. ILLINOIS STATE POLICE EVALUATION PLAN

The goals and methodology are described for the conduct and assessment of the Concentrated Traffic Enforcement Program that will be carried out by the Illinois State Police beginning 1 Sep 1977. Appended are district-wide objectives, illustrations of police routes, accident data for high-accident locations, and Illinois State Police operations instructions. Efforts will be directed at reducing vehicular accidents and their resultant injuries and deaths through increased police enforcement of all traffic laws at 45 state-wide high-accident locations. The six-month program (Sep-Dec 1977, May-Jun 1978) will utilize 49,280 man-hours, which will be devoted to patrol during critical days of the week and times of the day as suggested by accident patterns. This includes, but is not limited to, the two most dangerous periods: from 6 PM to 6 AM on Friday and Saturday nights. Additionally, public information campaigns will be conducted and judicial contacts made and maintained. The program's effectiveness will be measured by changes in accident frequency and severity.

SEAT/OCCUPANT CRASH DYNAMIC ANALYSIS VERIFICATION TEST PROGRAM

The Federal Aviation Administration is developing a computer modeling program (SOMLA--Seat Occupant Model: Light Aircraft) in an attempt to provide a practical engineering and design analysis tool for aircraft seat designers. To validate the model, two series of well-instrumented, controlled tests have been completed. Two basic seat configurations, two different impact vector orientations (forward-facing, and combined forward and downward), and two different impact levels were utilized to produce both elastic and plastic seat deformations. Measurements of seat reaction loads, seat belt loads, and dummy accelerations were made, and the tests were documented by high-speed motion picture film. Each test condition was repeated to obtain a statistical measure of test variability. The model, test program, and test results are discussed, as well as their implications for model development. The test data are appended. It is concluded that the response of the dummy used in the dynamic testing has been simulated rather accurately, particularly with respect to chest acceleration and belt loads. Attempts to simulate the response of the test seats have indicated that the present method of treating plastic deformation, by modification of elastic stiffness matrices, may not be suitable for analysis of seat frames that undergo large deformations. For frames that consist of elements whose stiffness are of the same order of magnitude, the model behaves well until a sufficient number of plastic hinges have been released to permit collapse of the structure in a rigid-body type of motion.

"THROUGH THE LOOKING GLASS" [ADJUSTMENT OF CAR MIRRORS]

Rough sketches are presented and discussed which approximate lines of sight (inside and outside rearview mirrors and their overlap) and the blind spot on the left observed from improperly and properly adjusted car mirrors. It is stressed that the overlap area between the fields of vision of the two mirrors should be minimal or nonexistent to increase viewing efficiency. The procedure for properly adjusting the mirrors is explained: The inside mirror is positioned to show the view directly behind the car, back to infinity; the driver, in his regular driving position and without moving his head, selects an object seen at the extreme left of the inside mirror, adjusting the outside mirror so that its right edge just excludes the selected object. A check is made to see that no blind spot exists between the two mirrors. A road test of properly adjusted mirrors shows that as a car approaches to one's left, it will disappear from the inside mirror just as it appears in the outside mirror. The driver is cautioned to be aware of motorcycles, and of blind spots that still remain to the right and left when driving on a road with three or more lanes in one direction. It is also advisable not to adjust mirrors on hills or curves, or when the car is not parallel with the road.

VEHICLE SPEEDS ON THE M1 MOTORWAY IN NOTTINGHAMSHIRE--1974-78

Vehicle mean speeds, traffic composition, and lane usage data were recorded on the M1 motorway in Nottinghamshire, England during Nov 1974-Dec 1975, Jan-Nov 1976, and Mar 1977-Nov 1978 under the same conditions (good weather, dry surface, off-peak, weekdays) as earlier measurements (1968-1969, 1969-1973). During Nov 1974-Dec 1975 immediately after oil crisis of Oct 1973-Oct 1974, mean speeds of passenger cars were about 2.5 mph below the immediate pre-crisis period (Oct 1972-Sep 1973), but speeds of goods vehicles (trucks) had fully recovered. Since 1975, mean speeds of cars appear to have increased by about 3 mph and those of medium and heavy trucks by about 1.5 to 2 mph. Up to Nov 1978, there was no sign that increasing fuel prices resulted in generally lower speeds. The percentage of cars on the road fell during and immediately following the 1973 crisis, but by 1978 had reached a new high level of 65.8%, reflecting continued increase in the level of car ownership since 1975. The continued increased of mean speed was also indicated by the increase in the percentage of cars using lane 3 (passing lane). It was also found that few drivers were deterred from using a section of the motorway being resurfaced, where the speed was restricted to 50 mph. Mean speeds of all vehicles over this section of the highway were reduced, those of cars up to 15 mph. Some 18% of cars exceeded the imposed 50 mph limit.

SAFETY COMES FIRST WHEN TRANSPORTING THE HANDICAPPED

Based on a presentation by Dob Donley entitled "Impact and Implementation of PL 92-142 and PL 504," which has been delivered at various meetings attended by transportation supervisors, a discussion is provided of procedures and equipment for the safe transportation of handicapped children in school buses. As president of a supplier of lighting fixtures for the school bus industry, Donley has access to various transportation systems. His research in the practices being implemented in transporting the handicapped student includes visiting various schools and taking photographs of school bus drivers and aides at work, and of equipment being used in school buses. The result is a slide presentation representing good and bad procedures and equipment, presented here with photographs taken from his collection of slides. Topics include involvement of the transportation supervisor, the restraint of wheelchairs in buses, the physical layout of the school bus, vest or harness restraints, covering certain bus windows to prevent glare, unloading and loading procedures, and emergency evaluation.

SUGGESTIONS FOR DRIVER TRAINING [TRANSPORTATION OF THE HANDICAPPED CHILD]

Information and helpful suggestions for drivers and supervisors in handling the transportation of the handicapped child are provided from the State of California School Bus Driver Training Course, Exceptional Child Unit, and from the Los Angeles Unified School District Handbook for Special Education School Bus Drivers. The various types of handicaps are described: educable mentally retarded, trainable mentally retarded, educationally handicapped, hearing handicapped, sight impaired, speech impaired, and orthopedically handicapped. The handling of behavior problems is discussed, emphasizing the need to recognize abnormal behavior and the role of medication in behavior changes. Loading and unloading processes are discussed, stressing the need for care and protection, the need to become familiar with all types of equipment used and worn by the children, and to know the extent of a student's limitations. The special characteristics of a special education bus driver are described: extra patience, alertness, emotional stability, personal warmth, understanding, etc. The crucial importance of cooperation between parents and driver/school is emphasized. Pertinent information about each child that should be provided to each driver is specified: name, address, sex, age, telephone number, type of handicap, picture of child, what to do if the parents are not at home when the child is returned from school; procedure to follow if the bus cannot reach the child's home; procedures if the child needs medical attention on the bus.

USED CARS

The various aspects of shopping in the used-car market are discussed in separate sections (individually authored) in this comprehensive guide for the prospective used-car buyer. The potential rewards in terms of price, choice, and availability are initially considered. A discussion of avenues for used-car shopping covers the use of the Sunday newspaper, weekly advertising "shoppers", and bulletin boards; communication of needs to friends and co-workers; the differences between dealer and private party sales; and the seasonal effect on car price. A checklist is provided of 50 steps in assessing the overall condition of the used car under consideration. Both major and minor points, requiring different degrees of effort and mechanical skill, are covered, including walkaround, underhood, cockpit, under carriage, and test drive checks. Advice is given to aid the consumer in determining the type of vehicle to look for, including the important factors of mileage and age, the type of use the car will get, the intended length of ownership, maintenance costs (especially price of replacement parts), and pricing guides used by dealers. Warranties are discussed in terms of types (original and used-car), components covered, length of coverage, obtaining information on a catalytic converter, extended policies, getting the warranty in writing and examining its specifics, and "as is" vehicles; some guidelines for purchasing a warranted used car are outlined. Factors to consider in determining whether to purchase a later-model used car as opposed to refurbishing one's present, older vehicle are discussed. A final section discusses the option of buying a used car from a rental agency (information provided by Hertz). Advantages include lower price, longer loan period for mechanic's appraisal, age limit of vehicle, and limited warranty.

STAYING AHEAD WITH [BICYCLE] HELMETS

An increased interest in offering bicycle helmets by various U.S. manufacturers is reported; sales of some 200,000 units are estimated for 1979. While each helmet manufacturer tests its own product and compares it to the competition, there are presently no standards for measuring helmet effectiveness. A set of voluntary standards by the Snell Foundation (California) have never been officially adopted. Dr. George Snively, the Foundation's director, states that the objective of a helmet is impact protection, to prevent the transfer of impact energy to the brain. The helmet requires some type of strap to keep it on the head, but there is some disagreement among manufacturers as to the best approach. The real dilemma in bicycle helmet design is to balance safety against comfort (e.g. weight, fit, ventilation). Among helmet manufacturers queried, none saw any immediate change in consumer resistance to buying and wearing helmets, and all thought that bicycle manufacturers could do more to promote helmet safety. Bicycle helmets are largely made by hand, and tremendous strides are being made in helmet design and production; for the future, more specialized helmets (e.g. one designed for children), and designs with lighter weight and stronger materials can be expected. Attached are advertisements for two types of bicycle helmets (leather and plastic).

MOPEDS: THE 200MPG ALTERNATIVE

Mopeds enjoy wide appeal among the young (about 20% of mopeds used primarily by persons 19 years of age and under), and are popular among senior citizens because of their price ($300 to $700), their fuel economy (average of 135 mpg), maneuverability, and effortlessness of operation. Mopeds are sensible for deliveries, for short trips to run errands, and for avoiding traffic jams. It is estimated that the moped could eventually replace 10% of all auto travel. Included in the practical advice in purchasing a moped is to buy a model with front and rear suspensions, and always to carry a spare spark plug when traveling by moped. All mopeds in the U.S. must have headlights, taillights, and an audible horn. Most mopeds have two-stroke engines that require between 1.5% and 4% oil mixed with regular gasoline. Some 50 companies (mostly European) distribute mopeds in the U.S.; a wide choice of optional equipment is available for the prospective buyer. Mopeds are easy for the amateur to repair; maintenance is relatively simple and infrequent; and parts are generally inexpensive and interchangeable from brand to brand. In most states, mopeds are legal on all streets except interstate highways; the minimum age for operating a moped is usually 15 or 16 years.

THE DAMAGED WHEEL SHOULD BE REPLACED

A recent field survey by a wheel manufacturer in three major tire markets revealed that one wheel in 70 upon which the tire dealer had mounted a new tire was sufficiently damaged to warrant immediate replacement. The survey also showed that the tire dealer was generally unaware of the scope of the problem and the conditions that require wheel replacement. Some common wheel damage conditions are described and illustrated to assist the tire service specialist in his own wheel inspection program. The causes, result, and corrective action for the following damage conditions are outlined and illustrated: bent rim flange, elongated bolt holes, excessive rust or corrosion, center or bolt-hole cracks, and splitting or cracking along wheel weld. Three steps to a successful wheel replacement program are provided: establish wheel inspection procedure, build customer awareness, and maintain a minimal wheel inventory.

DRUNK DRIVING COSTS, MORE THAN YOU MIGHT FIGURE

A true incident is related in which a regional executive for a state's alcoholism program was arrested for drunk driving. The executive made no attempt to hide his guilt, and was willing to take the consequences. He found that his attitude helped his employer to decide against suspending him from his job. Before his case came to trial, he signed up to attend classes in his own agency's Alcohol Highway Safety Program. When the case came to trial, the judge was willing to reduce the charge to impaired driving even though the breathalyzer test revealed a 0.15% blood alcohol level. The man kept his license and paid a fine. Shortly afterward, he received notification that his auto insurance had been cancelled. Subsequently, the one company that would insure him cost $791 yearly, vs. the previous rate of $385. These rates had to be carried for the next three years. The experience demonstrates that even the professionals who are aware of the influence of alcohol on driving behavior can become victims of the drug. A chart shows the additional insurance premium costs imposed on DWI offenders in various U.S. cities.

COURT DECISION ANSWERS QUESTIONS ON DRINKING AGE

In the case of J.C.'S Rock Saloon vs. William G. Milliken, the Federal District Court in Detroit has ruled that there is a rational and proper basis for raising the legal drinking age to 21, and even to age 25 if lawmakers or voters want to go further in combating drunk driving problems. Judge Ralph B. Guy, Jr. disagreed with the plaintiffs' argument that the state had no power, under the provision of the 14th Amendment, to make the legal drinking age different from the age of majority (18). He stated that states have been allowed to give differential treatment to various classes of citizens, based on age, providing there was a "rational" reason. The key question before the court was whether the voter-approved constitutional amendment, Proposal D, which raised the drinking age to 21 was a "rational" act. Plaintiffs argued that the sole basis for raising the age was traffic safety, which they contended was not a rational basis since older drivers (age 21-24) have similar driving records to those of younger drivers (age 18-20) in terms of alcohol-related accidents. Although Judge Guy agreed that the proponents of raising the legal drinking age to 21 had reasons other than traffic safety for their move, he said that the traffic safety issue alone was sufficient to satisfy the "rationality" test. Judge Guy's ruling included a discussion of the research of Dr. Richard Douglass of the Univ. of Michigan's Hwy. Safety Res. Inst. which indicated that lowering the drinking age in Michigan from 21 to 18 in 1972 was solely responsible for increased fatal accidents among 18 to 20-year-old drivers. Based on this conclusion, Judge Guy ruled that raising the drinking age to 21 was indeed a "rational" act. Guy also refuted plaintiffs' claims concerning freedom of religion, the fundamental right to drink alcohol, the rights of liquor licensees, and parents' rights.

SMOOTH, RIPPLE-FREE PLASTIC PANELS [AUTOMOBILE BODIES]

An "in-mold" coating method for compression-molded SMC (sheet-molding compound) parts has been developed by General Motors in conjunction with General Tire and Rubber Co. This process solves the surface blemish problem of producing smooth large plastic panels by casting a thin coating of a two-part urethane-polyester resin onto the part before it is removed from the mold. The first production parts with the molded coating were the header panels for the 1979 Pontiac Phoenix. The removable roof panels of the 1979 Chevrolet Corvette were also made by the new process. A different approach being perfected by Ford involves both a new material and a modification of the conventional compression molding process. PPG Industries' polyester resin (RS-50340) and Owens-Corning's glass reinforcement (No. 951) are the principal components of the compound. The main process variation is a pressure-reduction step before the part is fully cured. The first planned production part for the new material/process is the one-piece hood of the 1980 Econoline van. Two contenders with SMC methods for Class A surface automobile panels are reinforced reaction injection molding of polyurethane and injection molding of thermoplastics.

WHERE DID ALL THE GASOLINE GO?

The recent gasoline availability problem is not due to low stocks but because major oil companies decided to reduce deliveries to their dealers during the peak-demand summer months, a total reduction in allocations of more than 6% of 1978's supply (added on to a 3% increased demand). For unleaded fuel, the shortage is real; refineries have not been producing enough unleaded to keep pace with demand. In early 1979, 26% of primary stocks of gasoline was unleaded, while projected consumption was 36%. The amount of oil lost because of the Iranian revolution was never more than 1% of average daily U.S. consumption. Gasoline is amply available in the U.S., and will remain so, at increased cost. The demand for petroleum, even at a modest 2.5% industrial growth, will outstrip production in from 15 to 30 years. The Iranian situation has underscored the U.S.'s vulnerability to supplies of oil from OPEC countries, and has hastened moves to decrease this dependence. Various options to reduce domestic consumption of gasoline include weekend service station closings, coupon rationing, and allowing the price of gasoline to rise. The practical effect of station closings is to force 97% of the nation's gasoline sales into 62% of normal station hours. A coupon rationing ("white market") program is a government subsidy for one segment of the population at the expense of another segment, and the cost of administering the program is an added tax on everyone. Although price rationing would affect most those who are underprivileged, it should be possible to subsidize such groups through the income tax system. It is estimated that deregulation, which was initiated on 1 Jun 1979, will add 2 million barrels a day to the nation's output of crude oil by 1985 (more than twice the amount previously imported from Iran). Although alternate energy sources and revolutionary new engines are being explored, most people will have to learn to get by on less energy (by use of public transit, less recreational use of car, change in the number and types of vehicles owned, etc.). The role for the government is to develop a program that will end U.S. reliance on Middle Eastern oil (e.g. increased domestic production, and expanded facilities for distributing Alaskan oil).

CHANGES IN THE WAY YOU WILL TRAVEL. CITY TRAFFIC: WORSE BEFORE IT GETS BETTER. CAR OF THE FUTURE: SMALLER, LIGHTER, MORE COSTLY

Experts in every field of transportation were questioned about how Americans will travel in the years to come. The experts predict a gradual shift to airplanes for intercity travel, 82% of which is now done by auto. Buses and trains will prove more popular, especially for short journeys. These shifts from car use are the result of increasing fuel prices and the limited comfort of today's smaller cars, as well as of poorer road maintenance. Vacationers and others who make cross-country trips are also taking into consideration the rising costs of food and lodging. In crowded urban centers, people will continue to use cars, even if they do not want to, since mass transit systems in most areas are already having difficulty in accommodating rush hour demand; without a healthy boost in Federal spending, ridership is expected to grow only modestly. To relieve big-city traffic congestion, experts say, solutions include better traffic control systems, pedestrian malls, bike paths, car pooling, and special routes to speed bus travel. For the most part, bus systems, not subway networks, will be called on to handle commuters. New government regulations will make it easier for elderly and handicapped persons to use buses. Most experts agree that while there will be no massive shift to buses and subways in the next generation, the typical car of the future will differ in many respects from the one today. Automotive engineers and other authorities predict that cars will become smaller, lighter, and considerably more expensive. Most will have front-wheel drive, and more will burn diesel fuel or more exotic fuels (gasohol, methanol). More two-passenger urban cars, some of them powered by electricity, will be used for commuting to work and running errands. Experts say that tomorrow's family car is likely to resemble, at least dimensionally, recently introduced General Motors' compact cars. Additional improvements in fuel efficiency will be made, as well as in car safety and sophistication.

AUTOMOTIVE FUELS--OUTLOOK FOR THE FUTURE

Current and future supplies of petroleum-based and alternative fuels suitable for use in passenger cars and light trucks are examined. Prime movers and powertrains compatible with various alternative fuels, and General Motors' experience with these systems, are reviewed. Estimated ultimate petroleum reserves are about 70 times current world petroleum consumption; U.S. reserves are about 20 times current domestic petroleum use. In the short term for the U.S., the adequacy of petroleum supplies will depend primarily on imports, and also on government policy. At an annual growth rate of 3%, U.S. coal reserves (100 times greater than petroleum reserves) could satisfy domestic energy demand for about 120 years. Oil shale ultimate reserves are about twice those of coal; they are widely distributed and present environmental problems in production. If used in light water reactors of current design, uranium reserves could supply the U.S. energy need for less than ten years at a 3% growth rate; if used in breeder reactors, the supply will last 118 years. Solar energy's ultimate utility is severly limited by its unsteady nature and low conversion efficiencies. Gasoline and diesel fuel produced from oil shale appear to be most nearly cost competitive with similar fuels produced from petroleum. Synthetic gasoline and diesel fuel are the most desirable from the standpoints of density, exhaust emissions, and ease of transition. Economic incentives do not presently exist for synthetic fuels production. With respect to GM's experience, gasoline and diesel-like fuels are most desirable for heat engines. Less refined fuels could be used in continuous or external combustion engines, but might be detrimental in terms of emissions. Of the remote combustion systems which might use primary energy sources, battery electric on-board storage has the best potential.

FEDS, DETROIT LAUNCH ADAMS' SUPERCAR IDEA

Immediately following President Carter's brief "automotive summit" with top industry executives, Secretary of Transportation Brock Adams announced that the manufacturers had agreed to join with the government and scientific community in a cooperative, multimillion dollar research effort to help lay the technology base for the next generation of automobiles. The research goal would be to produce at affordable prices a conceptually different car within ten years that would reduce U.S. reliance on dwindling oil supplies. After the press conference, Adams discussed two research safety vehicles on display which had been built under the sponsorship of the Dept. of Transportation (DOT). At a subsequent DOT news briefing, Adams emphasized the need for a comprehensive research blueprint for advanced automotive technology and challenged the public to participate in upcoming regional hearing on the auto's future. The projected government/industry price tag of $50 to $100 million per year represents only 5% of the total cost to introduce a radically new vehicle, Adams admitted. Asked if the automakers could afford to pick up 95% of the ultimate tab for his "supercar", Adams warned that the automakers will have to spend money to stay in business. The research program is scheduled to begin in FY 1981. In addition to the public hearings, Adams said that DOT has set up a procedure to review the work of private inventors.

FUN-FLAT TIRES DUE OUT THIS FALL

Dunlop's Denovo 2 run-flat tire, introduced in Europe in Apr 1979, evolved from a conventional tire and wheel system. The original Denovo used a two-piece wheel with lubricant dispensers; a second version used Polygel lubricant applied to the underside of the tread. The Polygel seals punctures and provides a residual warm air inflation. The current tire uses the Denloc bead lock system and a one-piece rim. Dunlop claims that the Denovo 2 functions well in a deflated state for 100 mi at 50 mph, or if severely damaged, as by a long gash in the sidewall, will function safety for 50 mi at 40 mph. In 1978, the National Hwy. Traffic Safety Administration approved the Denloc concept. Dunlop has discussed direct deal and licensing agreements with several U.S. tire manufacturers. Firestone, Goodyear, and the auto industry recommend a dashboard warning light to indicate the run-flat mode, since the handling difference between the run-flat and normal inflation modes is very slight. The auto industry predicts that economic and psychological roadblocks will limit the use of run-flat tires in the U.S. for many years. Goodyear and Firestone are now developing run-flat prototypes with a reinforced sidewall. Goodyear estimates that its Self Supporting Tire will save 18 lb to 22 lb vs. a conventional five-wheel system with jack assembly, while Firestone's Advanced Concept Tires offer a 5 lb to 10 lb savings. Run-flats must match improvements made in conventional radials' rolling resistance plus the weight and space savings offered by their own temporary spares. In 1979, General Motors offers a precursor to the run-flat, Uniroyal's puncture sealant tire, as an option, while Firestone is considering introduction of the puncture-sealing Concept XXI, primarily a replacement tire.

REPAIR OF ALUMINUM HEAT EXCHANGERS [AUTOMOBILE RADIATORS, AIR-CONDITIONER COILS AND MANIFOLDS, HEATER CORES, AND OIL COOLERS]

Selection and application of appropriate techniques for in-plant and field repair of defective aluminum heat exchangers are discussed, including three flux (brazing, reaction flux soldering, noncorrosive flux soldering) and three fluxless (adhesive bonding, Gas Tungsten Arc Welding, ultrasonic welding) methods. Necessary equipment and consumables are designated, and step-by-step procedures outlined and illustrated by photographs. Two tables list the recommended in-plant and field repair techniques for such heat exchangers as radiators, air-conditioner coils and manifolds, heater cores, and oil coolers. Techniques for preparation of the area to be repaired are described.

THE RELATIONSHIP BETWEEN ENGINE OIL VISCOSITY AND ENGINE PERFORMANCE--PT. 4

Seven papers on the relationship between engine oil viscosity and engine performance were presented at a fourth symposium on the subject. Topics of the individual papers include the effect of viscosity on oil supply to the engine at low temperatures and low shear; high-shear studies of the viscous properties of engine oils in the laboratory; application of the present level of technical understanding to results from engine studies; and the role of viscosity in engine fuel economy. A review is presented of a major 1977 colloquium on the viscometry of multigrade oils.

INVESTIGATIONS TO CHARACTERIZE THE LOW-TEMPERATURE-FLUIDITY OF POLYMER-CONTAINING ENGINE OILS

The "W" portion of multigrade engine oils was previously classified only in terms of its low-temperature startability using viscosity measurements at -18 degrees C in the Cold Cranking Simulator. Because of the low shear rates encountered at the suction side of oil pumps, the low-temperature pumpability of the oils in the engine was not being considered. These studies were undertaken to correlate the low-temperature pumpability of multigrade oils in a full-scale engine with suitable viscosity measuremens with results of tests in laboratory pumping rigs. Comparative measurements of viscosities were obtained with different viscometers. A critical shear rate of 50 reciprocal seconds was found for the borderline pumping conditions of the test engine. Good correlations were found between viscosity data of a rotational viscometer and engine pumping data. With a special laboratory pumping rig developed for this project, very good correlations were obtained with the low-temperature pumpability of the engine. The temperature where borderline pumping occurs can be predicted equally well by the mean flow rates at the beginning of pumping or by the time when the first oil reaches the end of a capillary.

VISCOSITY AND FLOW PROPERTIES OF MULTIGRADE ENGINE OILS--A REVIEW OF AN INTERNATIONAL COLLOQUIUM

An international colloquium, held in Ostfildern, Germany on 7-9 Dec 1977, was attended by more than 250 persons from 18 countries. Speakers from 11 countries presented 24 papers. The program provided a comprehensive review of the state of the art of multigrade engine oils. In addition to discussions of the requirements of engines for specific oils and the fundamentals of rheology, the following main subjects were addressed: viscosity classification of engine oils development in the U.S. and in Europe; chemical and physical properties of viscosity index (VI) improvers; cold flow behavior and high-temperature viscosity of oils containing VI improvers; influence of mechanical, thermal, and oxidative stresses; engine performance of multigrade engine oils; and startability and pumpability of engine oils. Some of the most important results and conclusions concerning the relationship of engine oil viscosity to engine performance are reported and discussed; it has been shown that "effective viscosity" factors, such as temperature, shear rate, and pressure, are the keys for understanding the behavior of engine oils. It is concluded that possibilities for improving or extending the current viscosity classification system should be developed from the joint viewpoints of engine need, engine oil properties, and the tests required to correlate these parameters. The new classification system should include parameters such as pumpability properties at low temperatures, higher upper reference temperature, and shear rate effects on viscosity at high temperatures.

ASSESSMENT OF LUBRICATION CONDITIONS IN A BIG-END BEARING BY TEMPERATURE MEASUREMENTS--CORRELATION WITH HIGH SHEAR VISCOSITY

Following a description of test procedure and experimental oils, the temperatures recorded in the big-end bearing of a running engine are discussed in terms of viscous heating, effective viscosity, and high shear rate (HSR) viscosity as measured in a rotary viscometer. Results concerning the minimum effective viscosity for safe operation are compared with available published results. Results for big-end bearings seem to correlate with results for main bearings which are much easier to evaluate. Under hydrodynamic conditions, it is possible to derive an effective viscosity from temperature rise determination. A uniform shear rate cannot describe bearing operation over the entire range of oil viscosities. The HSR viscosity at 6 x 10 to the fifth power reciprocal seconds adequately describes the bearing operation only between 6 mPa.s and 12 mPa.s. Under 6 mPa.s, the effective viscosity is overestimated by present HSR measurements, mainly due to an increase of the bearing shear ate caused by lower film thickness. The viscosity limit for afest operation of a bearing depends on the bearing surface ondition, operating conditions, and additive package. With a worn bearing, failure can occur even with an SAE 50 oil. Comparison of present and previous research suggests that for current viscosity index values, bearing problems may occur for some SAE 20 oils, as defined by their HSR viscosity or, even better, by their effective viscosity.

A SIMPLE HIGH SHEAR VISCOMETER--ASPECTS OF CORRELATION WITH ENGINE PERFORMANCE

A simple rotary viscometer was constructed in which multigrade oils can be tested up to 150 degrees C and at shear rates of up to 4 x 10 to the fifth power reciprocal seconds. The apparatus has indicated the relative performance of oils, which differed in viscosity index improver but not in dispersant/detergent and antiwear additive treatment, in journal bearing wear and high-temperature cylinder bore wear tests. It demonstrably has not predicted differences in cylinder bore wear between lubricants, where these were due to the equally important differences in the reactivities of chemically-active additives. A viscosity classification test which can examine oils in a similar manner to this rotary viscometer could be a useful supplement to the existing classification test methods in indicating the rheologically-controlled behavior of multigrade oils in certain engine areas, although other nonrheological properties in the oil may be of over-riding importance. Lower shear viscosity data may prove to be more relevant to blow-by and oil consumption. It would be unwise to specify any single "safe" minimum viscosity value based on such a test, since engine conditions vary widely.

VISCOSITY EFFECTS ON ENGINE WEAR UNDER HIGH-TEMPERATURE, HIGH-SPEED CONDITIONS

Four multigrade engine oils, containing the same base oil plus SE additive package but viscosity index improvers of differing shear stability, were evaluated in 80,000 km of high-speed, high-temperature vehicle service. Bearing, piston ring, and valve guide wear, as well as oil consumption, oil filter plugging, and engine cleanliness were all worse for the engines operated on the low shear stability oils. The wear differences were traced to differences in high shear rate (HSR) viscosity, while the cleanliness, filter plugging, and oil consumption differences occurred because of excessive wear or polymer shear degradation. For the V-6 engines studied, the critical viscosity needed to prevent excessive engine wear was estimated to be 4.5 cSt (measured at 149 degrees C and a shear rate of 6 x 10 to the fifth power reciprocal seconds); this is in reasonable agreement with other studies. The results suggest that engine oil viscosity should be specified under HSR conditions.

AUTOMOTIVE ENGINE FRICTION AND FUEL EFFICIENCY--VISCOUS VERSUS NON-VISCOUS EFFECTS

The influences on fuel efficiency of viscosity differences and friction modification by colloid friction modifiers in motor oil were examined separately and in combination in a series of automobile track tests using Environmental Protection Agency test procedures. It was found that simply reducing the viscosity of multigrade engine oils did not produce consistent, statistically significant fuel economy benefits, but this was achieved by the incorporation of a colloid friction modifier. Although reduced viscosity multigrade oils did not show significant benefits over a commercial type SAE 10w-40 proposal S-1 oil, those same oils containing the friction modifier demonstrated significant fuel economy improvements over the commercial oil. The same improvement was found for a single grade (SAE 30) oil so modified. Fuel efficiency increases in the range of 5% to 10% are attributable to the friction modifier.

HS-026 516

A STUDY OF LUBRICATING OIL PERFORMANCE IN A JOURNAL BEARING RIG

Several polymer-containing oils were studied in a journal bearing rig under hydrodynamic lubrication conditions. For shear rates up to 2.5 x 10 to the fifth power reciprocal seconds and oil film thicknesses down to 2 micron, these oils showed the same behavior as polymer-free oils. In a second series of experiments, the bearing was provided with a suitable lining and experiments were conducted under boundary lubrication conditions. Bearing wear could be determined by weighing the bearing shells, and the results obtained showed that for Newtonian lubricants, wear increased markedly with decreasing viscosity. The influence of the performance package was demonstrated by two SAE 30 grades. A decrease in wear of about 60% was effected by a change of the performance package. For non-Newtonian lubricants, the wear level was lower than expected on the basis of high shear viscosity alone; an attempt to explain this behavior should take into account non-Newtonian effects and possibly the presence of films of absorbed material.

ELDERLY AND HANDICAPPED TRANSPORTATION: LOCAL GOVERNMENT APPROACHES

Approaches taken by a number of U.S. locatities in providing transportation to handicapped or elderly citizens are described. Some of these systems are Federally-funded, while some have developed from local initiatives. Some represent modifications to conventional public transit services, while some are special-purpose systems. Background information is given on the Urban Mass Transportation's Service and Methods Demonstration Prog., the identification of transportation priorities by the Transportation Task Force of the Urban Consortium for Technology Initiatives, and characterization of the transportation-handicapped population and their needs. Transportation systems for the handicapped or elderly individual are described for the following areas: Portland, Oreg.; Los Angeles County, Calif.; San Antonio, Tex.; Kinston, N.C.; Spokane, Wash.; Denver, Colo.; Ann Arbor, Mich.; San Diego, Calif; San Mateo, Calif.; State of Missouri; St. Louis, Mo.; Atlanta, Ga.; Los Angeles, Calif.; Philadelphia, Pa.; Dade County, Fla.; Boston, Mass.; State of Pennsylvania; and Washington, D.C. Lists are provided of the names and addresses of persons contacted in this investigation of existing systems, and of the members of the Urban Consortium Transportation Task Force. Selected characteristics of special and regular services of the various systems are presented in charts.

USER GUIDELINES FOR REDUCED VISIBILITY GUIDANCE SYSTEM DESIGN. EXECUTIVE SUMMARY

A recent study sponsored by the Federal Hwy. Administration is summarized. The study was undertaken to develop guidelines which would enable system planners to numerically estimate the need for a reduced visibility guidance (RVG) system, to select candidate systems tailored to plan requirements, and to estimate utilities and costs. The guidelines consist of a set of well-defined steps, as follows: quantify the need, define problem area characteristics, define major system elements, define adjunct system elements, make cost-utility comparisons, and select a system. Elements in each step are outlined in detail.

IGNITION CHARACTERISTICS OF FLAME RETARDANT FABRICS

Experimental measurements were made of ignition times and ignition frequencies under both convective and radiative heating on fabrics with and without a condensed phase active flame-retardant treatment. Minimum self-ignition temperatures and apparent molecular weight were also measured on pyrolyzate gases generated from two fabrics. It was found that the effect of flame-retardant treatment depends on heating intensity, fiber composition, heating mode, and level of treatment. Under some conditions the treatment effect reduces the hazard level; under others, the level is increased. Minimum self-ignition temperatures of the pyrolyzate-air mixtures generated from treated and untreated cellulosic fabrics were found to be dependent on the heating rate during the pyrolysis of the material. The temperatures decreased with increasing heating rates and with the flame-retardant treatment. Apparent molecular weights of the gases decreased with increasing heating rates during pyrolysis and with the flame-retardant treatment.

IGNITION CHARACTERISTICS OF SOME AIRCRAFT INTERIOR FABRICS

Six samples of aircraft interior fabrics were evaluated for resistance to ignition by radiant heat. Five samples were aircraft seat upholstery fabrics and one sample was an aircraft curtain fabric. The seat fabrics were 100% wool (2 samples), 83% wool/17% nylon, 49% wool/51% polyvinyl chloride, and 100% rayon. The curtain fabric was 92% modacrylic/8% polyester. The seat fabric samples were additionally evaluated in terms of resistance to ignition by a smoldering cigarette. Resistance was compared to fabrics of 100% cotton and 100% polyolefin. The wool-containing seat fabrics appeared to be superior to the rayon seat fabric in resistance to both types of ignition. None of the fabrics tested was identified with U.S. Airlines.

GOOD TO THE LAST DROP [IMPACT OF RESTRICTIONS ON GASOLINE USE ON THE AUTO SERVICE INDUSTRY]

Twenty-six service-related companies and trade associations were contacted for their views on how restrictions on gasoline use (voluntary or mandatory) might impact on the service business. Manufacturers of replacement parts did not believe that increasing the price of gas or asking car owners to reduce driving will lessen demand for service. Of 15 parts companies contacted, only three firms (Carter Carburetor, Sealed Power, and Holley Carburetor) indicated that they had considered any possible repercussions of the Administration's fuel-saving effort on the service business. Carter and Sealed Power did not appear to foresee any reduction in service volume, while Holley anticipates more cooperation on the part of companies to conserve fuel than on the part of individual car owners. Major trade associations (Automotive Service Councils, Motor and Equipment Manufacturers Assoc., Automotive Warehouse Distributors Assoc., Automotive Service Industry Assoc., Equipment and Tool Inst.) expressed similar views. One opinion was that, due to reduced disposable income, drivers will buy new cars less often, thereby requiring more service. Another opinion indicated that the need to increase fuel economy will lead to more frequent tune-ups and better maintenance of automobiles.

FILTER SERVICE

Filtration of contaminants in the automobile of today is as vital a function as supplying fuel and lubrication. The sophistication of the systems under the hood and chassis demands at least an equally sophisticated filtration effectiveness. The function, types, source of contaminants, service intervals, and servicing problems for the following types of automotive filters are discussed for the service specialist: oil, air, fuel, automatic transmission, coolant, crankcase breather air, and vapor canister. The special problems of diesel fuel filtration are outlined, including that of bacterial contamination. A chart denotes severe service intervals for inspecting or replacing filters and changing the oil. Some tips on "selling" filters are given. It is emphasized that factory "normal service" recommendations may not be enough when driving practices require more frequent "severe" servicing.

NO MORE GAS TANKS??

Solar Reactor Corp. (Miami, Fla.) researchers have discovered that a recyclable combination of light, hydrogen, and chlorine can be adapted to reciprocating, turbine, and rocket engines, totally eliminating the need for fossil fuel. Because the process is self-contained and recyclable, there are no exhaust emissions. The process is a revolutionary concept in harnessing energy wherein hydrogen and chlorine gases are allowed to react with air. Energy from light expedites the rate of reaction to produce a powerful explosion when air is introduced. Proper confinement allows this energy to be harnessed in the form of useful work. The process and its applications to internal combustion engines and turbine engines are covered under several patents. Solar Reactor, plus other labs, have run thousands of tests, repeatedly verifying the process while refining its applicability as a significant source of power. The process is approximately 14 times more energetic than gasoline combustion. Since the combustion products can be converted back to the starting fuel, self-contained power units using recycled fuel can be developed. One gallon of gasoline costs $1.00 and provides about 100,000 Btu's, while one gallon of 30% solution of hydrochloric costs $1.00 and provides 500,000 Btu's. Because light-activated chlorine and hydrogen combine explosively at one atmosphere pressure, piston kinetic engines would not require a compression stroke, resulting in increased engine efficiency of up to 80%.

THE END OF THE FAMILY CAR?

Lightweight diesel engine manufacturers say that the technology shows no signs of being able to meet the NOX (nitrogen oxides) emission standard of 1.0 g/mi in the 1981 model year, and the industry is applying for waivers to the Environmental Protection Agency (EPA) to set a standard of 1.5 g/mi. EPA also has set particulate emission standards of 0.6 g/mi for 1981 and 0.2 g/mi for 1983; the latter figure cannot be met by diesel engine manufacturers. The problem is that the method for reducing NOX in diesels involves exhaust gas recirculation, which increases particulate emissions by factors of 2 to 3. General Motors has proposed that a Corporate Average Particulate Standard be imposed to control the average levels of particulate emissions from a manufacturer's total car and light-duty truck production, both diesel and gasoline. The GM proposal involves standards starting at 0.2 g/mi in 1981 down to 0.05 g/mi in 1985, with a maximum permissible particulate emission of 1 g/mi from any individual diesel vehicle. The crucial challenge to the diesel, however, is the charge that diesel exhausts are carcinogenic. Diesel manufacturers have to prove that their engines will not pose an unreasonable risk to the public health. EPA apparently believes that its emission standards are proper and achievable, and that the only acceptable level of a risk of carcinogenicity is zero. The result of EPA action may be the abandonment of the diesel engine, which achieves better fuel economy than any gasoline engine of similar performance.

YOU'VE COME A LONG WAY, BABY!--ELECTRIC CARS, ONCE THE HEIGHT OF LUXURY ARE ON A DOE [DEPARTMENT OF ENERGY]-PAVED COMEBACK TRAIL

In a joint industry-government program, the Dept. of Energy (DOE) and a number of auto and electrical equipment manufacturers are attempting to update the public's knowledge of the new electric cars and to accelerate technological developments. Displays in 1979 at DOE reflect advances made since World War I; new electric car models, marketable today, from four small contracting firms have been exhibited. A DOE-funded conference held in Washington, D.C. on 25-29 Jun 1979 examined the state of the art and future technology. Chrysler Corp. and Globe-Union Battery Co., both as subcontractors to General Electric, unveiled the DOE-sponsored Electric Test Vheicle (ETV-1). In general, experts do not foresee a mass market for electric cars until the late 1980's. In mass production, it is estimated that the ETV-1 could sell for about $6400. Interestingly, safety was an important point in favor of electric cars in the first part of the century. Proponents point out the nonpolluting feature of electric cars, but speed is an issue that continues to plague the electric car makers. Factors that hurt the electric car in the early 1900's were inadequate recharging stations in rural areas, and higher initial cost and higher energy prices than for gasoline-powered cars. Today the gasoline price/ availability situation puts the electric car in a more favorable light, and the price of today's electric cars could be competitive in the future.

THE ENGINEER'S DIET. PT. 1

A driving/maintenance plan for an individual car owner to follow in order to reduce his car's fuel consumption is presented. Careful braking saves fuel. The difference in gas mileage for city vs. highway driving is almost entirely due to energy lost to braking in the city cycle. By avoiding traffic jams, a motorist can save gas as well as time. Careful planning of vehicle speed saves fuel. Mileage improvement is approximately linear from 55 mph down to the 30-to-40-mph range; below 30 mph, fuel economy typically begins to drop off. Fuel consumption increases at higher speeds; fuel economy may drop from 10% to 20% as speed is increased from 55 mph to 70 mph. Planning tire maintenance saves fuel. Fuel is consumed in overcoming rolling resistance, the primary contributor of which are the tires. Dropping the inflation pressure of a fully loaded radial from 24 psi to 16 psi increases rolling resistance by 31%, for about a 6.2% increase in fuel consumption. Increasing the pressure in the same tire from 24 psi to 32 psi brings only about a 2.2% improvement in economy, and 40 psi increases it by only an additional 1%. Somewhere around 30 psi is an excellent compromise between ride harshness and fuel economy. Tire pressure has an effect on fuel consumption at least as significant as the 55 mph speed limit. Driving slowly with a cold engine saves fuel at a minimal risk of increased engine wear. As soon as the engine will stay running, it should be driven away; prolonged warm-up is very wasteful. Combining as many short trips as possible into one long one also saves gas. An account of the Mobil Economy Run is provided in a separate section.

ENERGY CONSERVATION IN TRANSPORTATION

Twelve selections are presented from the literature generated by the energy crisis of 1973-4, for acquainting the non-technical reader with some of the terminology, policy issues, problems and solutions proposed, as well as for showing the range of responses to the issue. Eleven chapters are based on a study or document sponsored by a U.S. Government agency and chosen to illustrate a particular approach to energy conservation in transportation as seen at the time. Some of the recommendations were later incorporated into Federal policy; others were not. The twelfth selection assembles critical data developed since the energy crisis. The first section deals with private motor vehicles, discussing the impact of the energy crisis on daily household travel and public attitudes toward the energy shortage, the implications and consequences of the 55-mph speed limit, the effectiveness of carpooling, and the rationale underlying the fuel economy standards imposed for 1981 through 1984. Mass transit is considered as a more energy efficient alternative to the automobile, with possible ways of encouraging a shift from private automobiles to mass transit, and two methods of providing increased transit capacity to meet the growing demand. Improvements in rail freight transportation are proposed, and the intercity passenger train is discussed in relation to energy consumption and conservation. Strategies for airline fuel conservation are developed and analyzed. The most currently available analysis is presented of energy demand and conservation in all these modes of transportation, plus waterways and pipelines. The original reports are available from NTIS.

AMA [AMERICAN MOTORCYCLIST ASSOCIATION] VS. EPA [ENVIRONMENTAL PROTECTION AGENCY]: TAKING THE DB TO DC [MOTORCYCLE NOISE]

The Environmental Protection Agency's (EPA) proposal for a five year reduction in new motorcycle noise levels is opposed. The EPA would "certify" each new machine's quietude at a cost to the buyer of $200 to $400 per motorcycle. Opposition to the proposed regulations in 1978 was so strong, with nearly 60% general opposition and nearly 90% from motorcyclists, that the EPA gave up its attempt. In spite of the claim of the American Motorcyclist Association (AMA) that the proposal would be inflationary, it was renewed in 1979. An active campaign against it is urged. Ed Youngblood of AMA stated (May 1979) that the AMA favored a uniform nationwide standard for motorcycle noise, but found EPA'S plan inflationary and unreasonable. EPA's own data reveal that 88% of American motorcyclists (6 million people) maintain quiet machines at 83 db(A) or less; only a minority modify or fail to maintain their exhaust systems. EPA's plan does nothing to attack this real minority source of excessive noise. Estimates of the cost increase involved vary from EPA's possible $140 for 78 decibels, to the Council on Wage and Price Stability's (COWPS) $375 per vehicle, and some manufactures' $400. Charts demonstrate the cost to the motorcycle owner and the disproportion of costs vs. benefits. A survey among members of the AMA showed consumer acceptance of the increase involved in accepting the new standards dropping off rapidly beyond the $50 figure. The COWPS also found any reduction beyond 83 db(A) of questionable value, and beyond 80 db(A) intolerable and totally unjustifiable.

DRIVER IMPROVEMENT. IMPRISONED TRAFFIC OFFENDERS AS A TARGET GROUP FOR A PROBLEM-ORIENTED TRAINING PROGRAM (DRIVER IMPROVEMENT. INHAFTIERTE VERKEHRSSTRAFTATER ALS ZIELGRUPPE FUR EIN PROBLEMORIENTIERTES TRAININGSPROGRAMM)

A final report is made on Phase 2 of the project "Driver Improvement--Development of Psychological Measures for the Rehabilitation of Traffic Offenders." To develop a training program for traffic offenders utilizing the principles of learning theory, sociodemographic data and information on driving records were collected on approximately 70 persons participating in the courses. Analyses of court records and questionnaires answered by the participants are discussed and evaluated. A description is given of the further development of "problem-oriented training" for drivers tested initially at one penal institution as a preparation for the organization of courses at various Austrian institutions. The main modifications in this training, which includes elements of patient oriented psychotherapy and of group dynamics, in addition to elements of behavior therapy, consisted in extending the number of group sessions from four to six, each lasting 2 to 2-1/2 hours, and in emphasizing guidance in self-control. The plan of study for Phase 3 is given, emphasizing the necessity of taking supplementary measures as soon as possible to use this training program as a preventive measure.

NATIONAL TRANSPORTATION POLICIES THROUGH THE YEAR 2000. FINAL REPORT

Findings and recommendations are presented on the following issues: the nation's transportation needs, both national and regional, through the year 2000; the ability of our current transportation systems to meet the projected needs; the proper mix of highway, rail, waterway, pipeline, and air transportation systems to meet anticipated needs; the energy requirements and availability of energy to meet anticipated needs; the existing policies and programs of the Federal government which affect the development of our national transportation systems; and the new policies required to develop balanced national transportation systems which meet projected needs. Baseline information is provided on current transportation activities and institutions, on present Federal, state and local transport policies and programs, and on those of other developed countries. Three scenarios are presented to encompass future economic and social anticipations, with technological changes specific to transportation and communications affecting transport markets up to the year 2000. The effects on pollution and safety resulting from and influencing transport forecasts are presented, as well as energy demand and supply projections. Forecasts are made of passenger and freight activity from 1975 to 2000, by market rather than by mode. Capital requirements of all transportation demand forecasts are estimated. All the National Transportation Policy Study Commission forecasts, except petroleum regulation, were based on status quo policy assumptions. New policies are recommended to develop balanced transportation systems under the following six major policy themes: national transportation policy should be uniform; there should be an overall reduction in Federal involvement; economic analysis of intended Federal actions should be used; when the transportation system is used to pursue social goals, it should do so in a cost-effective manner; Federal involvement in (including financial assistance for) transportation safety and research is required; and users and those who benefit from Federal actions should pay.

HOW DOES COMBUSTION RATE AFFECT NOX [NITROGEN OXIDES] EMISSIONS?

An attempt was made to clarify the effect of varying combustion rate over a range of engine speed, load, EGR (exhaust gas recirculation), octane number, and compression ratio (CR), on NOx (nitrogen oxides) emissions and fuel consumption. The study involved firing one, two, three, four, or five spark plugs in a single cylinder Ricardo E6 engine equipped with an open disc combustion chamber. The use of multiple spark plugs increased the combustion rate of the air-fuel mixture charge, which varied with firing spark plug position. Extreme values of speed, load, and number of ignition points showed that by using four spark plugs, the burn time could be halved, while brake specific NOx increased by 13% to 113% and fuel consumption decreased by 7% to 28%. There was only a slight difference in fuel economy between slow and fast burn conditions when varying the air-fuel ratio (A/F). Reducing the burn time increased the NOx emissions for all loads, fuels, and combustion systems. Indicated specific NOx (ISNOx) emissions were not a unique function of burn rate. Spark plug two (closest to exhaust valve) gave significantly more NOx than others. The addition of a shrouded intake valve reduced ISNOx emissions at light load and increased combustion rate. Addition of extended electrode spark plugs increased NOx and combustion rate in some cases. ISNOx increased with combustion rate at zero EGR rate, and decreased while combustion rate increased at high EGR rates. As the EGR rate increased, NOx levels became increasingly higher than corresponding levels at 7:1 CR at the same burn rate. Increased CR gave decreased burn time. The crossover EGR value above which shorter burns reduce NOx was over 20% EGR rate at 18:1 A/F. A study of the effect of combustion rate on octane requirement showed that the tendency to knock with four spark plugs operating was greater at lower CR's associated with lower octane fuel than it was at higher CR associated with higher octane fuel.

POWER STEERING SYSTEM VARIES ASSISTANCE WITH SPEED

A velocity-sensitive type of variable-assist power steering introduced by Honda provides full steering assistance at low speeds, gradual reduction in assistance with increasing vehicle speed, and a normal unassisted "road feel" at highway speeds. The device operates on a rack and pinion steering gear, and is powered by a gear-type hydraulic pump driven by the engine. The speed sensor is a trochoid-gear hydraulic motor, driven by the pressure in the speed sensor line with its rotational speed governed by the speedometer gear shaft in the transmission. This power steering system causes the maximum amount of steering effort at a given speed to be governed by that speed, regardless of road surface resistance. The driver road feel is proportional to the road resistance, and the front wheels are turned by both hydraulic power and driver effort. In the event of failure of the system, the steering will revert to manual control. A failure in the speed-sensing mechanism results in more steering effort at low vehicle speeds rather than excessively light steering at high speeds.

DIESEL INJECTION RATE CAN MINIMIZE EMISSIONS, MAXIMIZE ECONOMY

Swirl-type direct injection (DI) diesel engines show marked differences in their response to increased injection rates, probably due to differing degrees of liquid impingement on combustion chamber walls resulting from different air inlet ports, air motion, and corresponding best nozzle configuration. A "rate parameter" correlates fuel injection rates with BSFC (brake specific fuel consumption), smoke, carbon monoxide, and nitrogen oxides (NOx) for non-impingement conditions, but beyond a "maximum useful rate" (MUR), NOx continues to increase while there are no further reductions in the first three items. Overall optimum impingement rate is less than MUR in practical cases, and is a function of various emissions and system response to injection rates and timing. In principle, an injection rate corresponding with the MUR should be used to obtain best possible fuel economy and least smoke regardless of emissions and noise. High-swirl, impinging DI engines require only a 15% injection rate increase for best fuel economy and least smoke, and this can be achieved with present injection equipment. A non-impinging DI engine requires a 33% injection rate increase relative to currently used values, with a consequent increase in fuel injection equipment cost. NOx emissions can be reduced by retarding fuel injection timing. An injection rate increase may then be beneficial in minimizing BSFC or smoke increase associated with injection timing retard. Optimum injection rates for best BSFC and smoke, combined with NOx emissions of about 8.7 g/kW.h, varies from 0% to 25% above normal fuel injection rates, depending on design. Computer model calculations show that very short burn-times to improve cycle efficiency have a penalty of increased convective heat loss with increased fuel-air mixing rate. These calculations also indicate the relative cycle efficiencies for high swirl mixing systems of an indirect injection engine, a conventinal swirl DI engine, and an adiabatic engine.

POWERPLANT EFFICIENCY PROJECTED VIA LEARNING CURVES

An approach to technological projections for automotive powerplants can be based on learning curves such as those characterizing certain human efforts. Historical learning curves can be constructed for such alternatives as the diesel engine, gas turbine, rotary, and other powerplants. Since most developments proceed along evolutionary paths, projections of their progress toward 1990 may be made, using a range of plausible slopes. Learning curves are presented and discussed which provide insight into the development and fuel economy potential of various types of automotive engines, including prechamber and open chamber stratified charge internal combustion engines, turbocharging of diesel engines, dual displacement and variable displacement engines, the Stirling and Rankine engines, and combined cycle engines. The curves are based on fuel-economy-related work which was mainly sponsored by the National Hwy. Traffic Safety Administration.

ON-BOARD COMPUTERS MAY PROVIDE DASH DISPLAY INPUTS

On-board computers (OBC's), now available on certain car models, because of their versatility and cost-effectiveness may become part of the basic instrumentation package. In the Ford Versailles, the Electronic Engine Control provides an integrated control of the exhaust gas recirculation. The next level of improvement of OBC technology beyond interaction control will be adaptive control. Three important adaptations will enable OBCs to sense the actual component functions as they come together in a specific car and to adjust the powertrain controls for the unique combination of parts. Adaptation to altitude and temperature changes will be possible, as well as to driving conditions, possibly also to road surface and changing tire characteristics. Adaptation to system changes occurring over a longer time period may follow. In vehicle control applications, rapid logic operations, interrupt servicing, and multichannel output are more important than a large data base access. Therefore some form of distributed computer might be cost effective as applications spread throughout the vehicle. This approach simplifies the integration of dedicated or "stand-alone" electronics. In programming, the tiny read-only-memory unit completely defines the control function and stores the quantitative information specific to a car/engine combination. On-board computers may be made responsive to driver demand; many items of information buried in the engine control logic might be of interest to the driver. Diagnostic programs for preventive maintenance are also possible with the OBC.

MATERIALS CHANGES AFFECT COOLING SYSTEM PERFORMANCE

Substitution of light alloys in automotive cooling systems must be accompanied by full consideration of their corrosion characteristics. The coolant should be recognized as a critical material, and a full-time, functional fluid. The use of a 50% to 70% mixture of a well-inhibited antifreeze-coolant will result in greater corrosion protection attributable to less coolant pump cavitation, reduced nucleate boiling erosion, and increased metal passivation. The basic mechanisms involved in cooling system corrosion are direct attack, electrochemical corrosion, and cavitation erosion. Three types of organic and inorganic inhibitors (anodic, cathodic, and adsorption) are used in anti-freeze-coolants to minimize corrosive attack. No single inhibitor will protect all cooling system metals. The proper selection of an inhibitor combination depends upon the metals used, composition of the coolant base, flow conditions, environmental temperatures, and heat flux at the heat transfer systems. Factors accelerating corrosion include galvanic couples, aeration, exhaust gas leakage, corrosion products, metal stresses, localized hot spots, high coolant operating temperatures, poor quality water supplies, and certain coolant flow characteristics. Aluminum coolant pumps are vulnerable to cavitation-erosion-corrosion in the presence of improperly inhibited, depleted, or diluted coolant. The extent of damage and the tendency to perforate is influenced by the pump design, as well as by improper fitting of hoses and hose clamps.

TORCH IGNITION SHORTENS COMBUSTION DURATION

The power and efficiency losses that normally accompany the slow burning of lean mixtures may be reduced by using a torch ignition system. The torch chamber provides turbulence which can reduce the combustion interval and possibly reduce exhaust emissions. The use of a directed torch nozzle enables the optimum torch jet direction to be found. In recent testing, a late-firing torch, in conjunction with a standard ignition system, was used to provide additional energy to supplement cylinder turbulence. The use of the late-firing torch provided a reduction in hydrocarbon emissions but increased fuel consumption.

AIR-TO-AIR HEAT EXCHANGERS USED FOR DIESEL INTERCOOLING

An air-to-air intercooler system has been developed by Volvo Truck Corp. for cooling the charge air of its turbocharged diesel truck engines. The method is considered to be simpler and more efficient than air-to-water intercooling, with high reliability due to absence of moving parts. The system routes charge air from the outlet of the turbocharger through a heat exhanging radiator (mounted in front of the truck's regular radiator) and thence to the intake manifold of the diesel engine. Exhaust emissions are also decreased, primarily smoke and oxides of nitrogen. The increased air/fuel ratio improves combustion; specific fuel consumption should be improved as a result of better efficiency. The Volvo 6.7-L turbocharged diesel engine is made in two versions: the TD70G engine, the ordinary 156.6 bkW (210 bhp) version, and the TD70F, the same engine with air-to-air charge air cooling. Output of the TD70F is increased to 171.5 bkW (230 bhp) with the addition of the charge air cooler, which adds 22.7 kg of mass to the engine. A photograph and three diagrams illustrate the coolers.

THE IMPACT OF THE SMALL CAR

Conditions and events causing the trend to small cars are discussed. Social changes, legislation, the capabilities of the carmakers, and the energy question are all crucial and interdepedent factors. For over a decade government regulations have set up technological objectives to produce safer, cleaner cars (90% cleaner in hydrocarbon emissions than the pre-regulated cars of the 1960's, 82% cleaner in carbon monoxide emissions, and 51% fewer oxides of nitrogen). With the development of the fuel-efficient small car, the carmakers foresee a need for more service outlets and highly skilled mechanics, with a great increase in parts inventories throughout all levels of distribution. The stocking up of parts and accessories for small cars by the retailer is seen as essential, since the change from large to small vehicles is a permanent one. The recent increase in the van/light truck market supports the idea that practicality is a growing consideration. Figures for the first three months of '79 suggest that of the million-plus vehicles sold, nearly 60% fall into the compact, sub-compact or import categories, and it is estimated that by the 1980's at least a third of the market will fall into the subcompact category. Studies show that Americans are holding onto their large, older cars longer, because the purchase of a new small car is not always cost-effective for those families who still need a larger car or light truck. The challenge to the vehicle industry is to continue to provide at least some of the service mobility, comfort and convenience that the public needs and expects.

TIRE TECHNOLOGY FOR THE TIRE DEALER

Principles of tire manufacture are presented to assist tire dealers in discussions with customers and in training personnel. Tire functions are listed as carrying loads, transmitting driving and braking torque, cushioning road irregularities, developing cornering and directional stability forces, providing mobility, and avoiding flotation, as well as providing low heat buildup, low rolling resistance, and high abrasion resistance. Main tire components include the casing, the bead, and the rubber covering. Trends in the tire market, and tire volume vs. raw material consumption are discussed. A table of the weight breakdown of tire materials by size and construction is provided, as well as a glossary of tire terms and schematics of cross sections of a bias truck tire and a steel belted radial passenger car tire.

MISAPPLICATION OF TREAD RUBBER CAUSES POOR BOND LINE ADHESIONS, TIRE FAILURE

Recent National Tire Dealers and Retreaders Assoc. investigations reveal that among several factors contributing to inadequate bond line adhesions and tire failure, the two most common are heat and the oil content carbon black combinations in lower grade or highly oil-extended compounds. Misapplication of tread rubber (using a low-grade passenger car tread rubber for truck tire retreading) causes flex fatigue problems resulting in premature chunk outs or tread lifts, especially in hot weather. Data from laboratory bond line adhesion study on five grades of tread rubber from the same manufacturer show that the better grades have superior heat aging and flex fatigue properties. Laboratory studies also show that physical properties of tread rubber deteriorate rapidly at sustained elevated temperatures. Use of highly oil-extended tread rubber compounds could create an oil migration problem at an interface (the buff line, in retreading) when a difference in oil concentration exists between two rubber stocks. The migration of oils from the uncured treat rubber to the buffed casing alters the physical properies of both, and contributes to flex fatigue problems. In separate sections, a news item indicates that the energy crisis will increase the volume of retreading business, and correct methods of repairing nail hole punctures are explained and illustrated.

CAR MAKERS. WHERE THEY'LL TAKE US TOMORROW

It is predicted that the internal combustion piston engine will continue to be the chief automotive engine in 1985. Fuel saving features will include such changes in the drive train as lock-up torque converters, built-in over-drives, changes in gearing, and more speeds. Run-flat tires, eliminating the spare, and high pressure radials will be more common, with fabricated aluminum and high-density fiberglass wheels envisioned in the future. Factors influencing automotive technology after 1985 will be need for energy sources other than conventionally derived petroleum, need for further fuel economy improvement, and control of emissions and pollutants. Electronics will be important in providing precision of engine control; the three-way catalyst, soon to be a key emission control device, requires accurate control of the fuel/air ratio; the electronic feed-back carburetor is a comparable component. More sophisticated computer-controlled systems are planned for the next few years. In weight reduction, the key materials are aluminum, plastics and high strength steel, all of which will be used more in the '80s. Other changes include greater use of thin glass to save weight, and of more galvanized steel, special paints and treatment for corrosion control. A possible reduction in the price of graphite fibers would permit their use in structural applications as graphite-reinforced plastic. Changes in design and in engine and drive-line components are cited for the 1979 model year. Charts show current and future projections of the movement toward smaller cars in the domestic and import markets.

OFFICIAL WATCHDOG...A MOTORIST'S BEST FRIEND?

Gordon Borrie, since 1976 the Director-General of the Office of Fair Trading in Britain, finds that motoring complaints take up the greater part of his department's time. In 1978, when a survey revealed that 67% of all new cars needed repairs in their first five months on the road, he notified the responsible companies, allowing time for corrections; if the percentage continues as high, he plans to make his findings known to the public. Mr. Borrie has campaigned against the "rogue" car dealers, usually not members of the motor trade associations, who turn back mileage readings on used cars, make unnecessary or botched repairs, and sell unroadworthy cars. He estimates that such unscrupulous firms were responsible for a majority of the 60,000 car complaints his office received in 1978. A network of trading standards officers throughout the country monitors complaints and gathers facts about local "problem" firms. His powers included, since July '78, the authority to withhold, suspend or revoke a Consumer Credit Act licence, by which a dealer arranges hire purchase for his customers, and to demand a written promise of future good behavior from an unfair dealer with the sanction of court action if the promise is refused or broken. These powers are limited in comparison with those of his counterparts in a number of European countries, and their effectiveness is still to be determined. Various codes of practice can be devised to protect motorists, such as regulations for the selling and service of tires, and a major code, operating since 1976, covering new-car deals and repairs. Compulsory membership in a trade association is opposed, as it would cut competition and drive up prices, and the public may get as good or better service from a small garage as from a large concern.

SAFETY-RELATED INFORMATION NEEDS. A REPORT TO THE FEDERAL HIGHWAY ADMINISTRATOR FROM THE SAFETY-RELATED INFORMATION NEEDS TASK FORCE

A study initiated in 1978 of FHWA'S safety-related information needs includes accident data, data relating to exposure to accidents and to costs of accidents and countermeasures, as well as other information. The study was designed to determine the safety-related information needed to the foreseeable future for carrying out FHWA'S motor carrier safety and highway programs. This included evaluation to insure that only the most essential information is collected, identification of potential sources for supplying critical missing data, and determination of resource requirements for providing and utilizing needed information. A 10-person task force was established. After presenting the legislative background of Federal highway safety programs the report describes the study approach, and lists results of the analysis. These provide documentation of current and foreseen FHWA safety-related information needs, with systematic priority ranking of such needs, and classfication of information items as to importance, availability, usability and sources. Recommendations are made, designed to lay a foundation for administering the program, building upon resources currently existing in FHWA, the States and other public and private organizations. Tables listing program areas, decisions, and information data are appended.

SEAT BELT LAWS: IMPLICATIONS FOR OCCUPANT PROTECTION

Laws requiring seat belt use have had some limited success in reducing occupant fatalities, although fatality reductions have been considerably less than expected from the reported increases in belt use rates. Belt use by persons involved in crashes has not increased to the same extent. Occupants most likely to be in serious crashes are least likely to increase their use of belts in response to laws. Many involuntary belt users comply with belt use laws by wearing their belts incorrectly, in ways that greately reduce their effectiveness. Many persons in front seats who wear belts in response to laws are susceptible to being impacted in crashes by unbelted rear seat occupants. It is recommended that laws apply to all or most vehicle occupants, that there be no weakening of the law once passed, and that there be strong enforcement and appropriate publicity. The incomplete success of belt use laws does not reduce their importance, but does reinforce the importance of providing automatic ("passive") protection to vehicle occupants as an alternative or supplementary measure.

SOME PSYCHOPHYSICAL TESTS OF THE CONSPICUITIES OF EMERGENCY VEHICLE WARNING LIGHTS

Some exploratory studies are reported, aimed at evaluating the conspicuities (attention-attracting powers) of a group of commercial warning lights meant for use on emergency vehicles. The main experiment used a novel technique of conspicuity matching: each observer, in turn, fixated straight ahead and viewed two flashing lights peripherally, one located 20 degrees to the left of the fixation point, and one 20 degrees to the right. One of the two lights was always a reference light whose intensity could be adjusted by the observer until the two lights appeared equally conspicuous. All the lights were thereby ranked on a single scale of conspicuity, based on the adjustable-light intensities. There was a good correlation (r=0.90) between these ranks and the measured effective intensities of the lights. Another very brief pilot experiment ranked some of the lights according to the number of degrees into the left side of the visual field that the flashes could still be seen. This disappearance-angle rank also correlated well (r=0.86) with conspicuity rank. Among the problems encountered was the discovery that several of the test lights were more conspicuous than the reference light set at maximum intensity; this was solved by the use of a fixed neutral filter in front of the test lights. A procedural difficulty involved a partial fading of the visual field after steady gazing at the fixation cross; it is suggested that in future work a more limited, nonrigid kind of fixation be used. The rating of the tested commercial lights is tabulated and discussed. The feasibility and reliability of the new conspicuity-rating method are discussed, including the method's relationship to other measures. Results of a limited study of the effects of color are described. Future comparable experiments are recommended with variable factors affecting conspicuity.

HIGHWAY ACCIDENT REPORT. STATIONWAGON PENETRATION OF BRIDGERAIL, I-10, NEAR ALHAMBRA, CALIFORNIA, NOVEMBER 11, 1978

About 3:40 p.m., p.s.t., November 11, 1978, a station wagon with 13 occupants exited from Interstate 10 onto a branch connection ramp. It was raining and the roadway was wet. As the station wagon negotiated the ramp, the driver lost control of the vehicle and it crashed through the bridge rail and fell to the roadway below landing on its roof. The driver and six passengers were killed and six passengers were injured. The National Transportation Safety Board determines that the probable cause of this accident was the driver's loss of control of the station wagon on the branch connection ramp, which resulted from the road surface's low coefficient of friction, the speed of the vehicle, the degraded condition of the vehicle, and the intoxication of the driver. The severity of the crash was magnified by the failure of the bridge rail, known to be inadequate by current standards, to retain the vehicle. Recommendations made to the State of California were: Until the accident site is improved, install "Slippery When Wet" warning signs and a 25-mph speed advisory sign; establish a policy and program consistent with Federal Hwy. Administration guidelines and standards to provide for upgrading substandard bridge railing that has been crash-damaged; expedite action on safety improvement at the accident location; and establish a program to retrofit, on a priority basis, bridge railing that does not meet Federal performance guidelines.

HIGHWAY ACCIDENT REPORT. GATEWAY TRANSPORTATION COMPANY, INC., TRACTOR-SEMITRAILER PENETRATION OF MEDIAN BARRIER AND COLLISION WITH AUTOMOBILE, I-70, ST. LOUIS, MISSOURI, SEPTEMBER 25, 1977

At 8:07 p.m. on September 25, 1977, an empty tractor-semitrailer was traveling eastbound on I-70 in downtown St. Louis, Missouri, when the truckdriver lost control of his vehicle on wet concrete pavement. The tractor struck, broke, and overrode a concrete median barrier, vaulted into the westbound lanes, and collided with a westbound automobile. All three occupants in the automobile died; the truckdriver was injured slightly. The National Transportation Safety Board determines that the probable cause of this accident was the loss of tractor-semitrailer control during evasive maneuvers made by the truck driver in response to improper lane changes by an eastbound automobile driver. Contributing to the severity of the accident were the barrier impact speed and attack angle of the tractor-semitrailer which may have only slightly exceeded the design limits of the functional "New Jersey" concrete barrier. Recommendations were made to the Federal Hwy. Administration for development of a more progressive pavement surface improvement program in Missouri, and for improvement in the performance of concrete barrier systems already in place. Recommendations to the Misouri State Hwy. Commission included corrective action in traffic routing and improvement in wet pavement surface policy.

ISN'T IT TIME? [MOTORCYCLE RIDER EDUCATION]

The continuing dispute between government and motorcyclists over the helmet law overshadows more meaningful safety programs. Creation in 1973 of the Motorcycle Safety Foundation (MSF), funded by the five largest motorcycle manufacturers, stemmed from their concern about the lack of government leadership in motorcycle safety, especially in the area of education. After defining the 2,500 tasks a motorcyclist must perform, the MSF, with funding from the National Hwy. Traffic Safety Administration, developed a study to determine whether a particular skill is best taught via film, still pictures, the seat of a motorcycle, or other means. Three years of research and testing produced in 1976 the Motorcycle Rider Course (MRC). Instructor certification programs were developed at colleges and universities. NHTSA, while funding an effective training program, questions the concept of rider education, and advocates further preliminary study with a four-year demonstration project. Officers of the MSF oppose further delay. Illinois, when threatened with withdrawal of Federal highway funds because the state had no helmet law, asked if the money would be released for an education program, and this was allowed. This solution, if carried out in the other 49 states, might have turned the helmet controversy into a nationwide rider education breakthrough. In Illinois a training program based at seven regional centers has taught 11,000 beginning motorcyclists, with another 7,000 in training. Except for North Dakota, no political backing has been developed in any of the states for legislation on rider education. Programs for motorcycle safety training can best be promoted by individual cyclists, working in their communities. An accompanying article describes the development of a benchmark rider education bill in North Dakota, where ABATE now stands for American Bikers Aiming Toward Education. A $5 surcharge, added to the state's $6 motorcycle license fee, is used for rider education; the North Dakota Motorcycle Dealers Assoc. supplies training bikes for high schools wishing to offer the program. The only remaining hurdle is to persuade school districts to offer the course.

TIME FOR CHAIN MAINTENANCE [MOTORCYCLES]

Methods are discussed and illustrated for proper adjustment and lubrication of a motorcycle chain, as well as evaluation of its condition for possible replacement. Precise alignment of the rear wheel is necessary for proper chain adjustment. Chain lubrication tips include application of lubricant to the edges of the linkplates, preferably while the chain is warm (after riding), and allowing the lubricant to soak in before riding the motorcycle.

1,849 FAMILIES REPORT THEIR AUTO CRASH EXPERIENCE

Auto insurance is the single most important source of benefits for persons injured in automobile crashes, according to a consumer survey of 1,849 families from the third major study conducted by the All-Industry Research Advisory Committee, which includes pending as well as resolved claims, plus information on benefit sources other than auto insurance. The families reported that auto insurance provided 67.5% of total reimbursement; group health insurance was next with 22.3% of total payment. All government benefit programs combined provided 5.6%, workers compensation 3.5%, and all other private insurance sources 1.1%. More than 97% of persons injured in auto crashes have at least one potential source of payment. About 92% of the families were covered by auto insurance and 84% by group health insurance. Only about 16% had collected from more than one source when economic losses were $500 or less; when losses exceeded $5,000, about 61% received payment from two or more benefit sources. As a group, persons who collected from a single source received an average of $1.42 for each dollar of economic loss sustained; for those collecting from two sources, payments equalled $1.33 for each dollar of loss; the few collecting from three different sources averaged $1.56 per dollar of loss. Persons with small economic losses received more reimbursement per dollar of loss than those with large losses, under all types of benefit sources, government as well as private. Payments in relation to economic loss were higher for persons whose injuries produced no permanent disability than for those with permanent physical impairments. Residents of large cities collect the most reimbursement per dollar of economic loss. Enactment of no-fault laws has caused changes; auto insurance provided a larger percentage of reimbursement in the no-fault states than in the traditional tort states, while group health insurance provided slightly less reimbursement in the no-fault states than in the tort states. Of the 1,849 respondents in the survey, 407 had not received payment from any source although some still had claims pending or had not yet filed a claim. The uncompensated persons tended to have small losses (2/3 had losses of $300 or less) and were concentrated in rural areas where single-vehicle crashes are more prevalent. A disproportionate percentage came from the tort states, where fault is often a bar to reimbursement.

AUTOMOBILE INJURIES AND COMPENSATION: THE AIRAC [ALL-INDUSTRY RESEARCH ADVISORY COMMITTEE] STUDY

A report of three separate studies by the All-Industry Research Advisory Committee indicates that persons in the 16-24 age group, who make up 17% of the population, accounted for over 30% of the injuries covered by insurance, especially catastrophic injuries. Persons under 16 and over 65, had fewer incidents of auto-related injury than their population share, and the 25-64 age group reported auto injuries roughly in proportion to their share of the population. The first study reported injury claims settled countrywide during a two-week period in 1977. The second study involved catastrophic injury cases (payments estimated at over $100,000) in Michigan, Pennsylvania, and New Jersey, where no-fault laws provide unlimited medical benefits. The third study surveyed about 60,000 families to identify those receiving injuries in recent auto accidents. The families reporting injuries (5%) were sent detailed questionnaires concerning extent of injury, economic losses (including wages), and compensation from various sources. The data from these studies indicate that young people present greater risk to an insurance company than older people; that auto injuries are a predominantly urban phenomenon (70% in closed claims study); and that injury claims are generated by persons other than the insured (policy holders were drivers in 60% of injury-producing accidents). The studies have provided data useful for evaluating the performance of the auto accident compensation systems in various states, including those with no-fault laws. No-fault is found to have brought major changes in methods of payment to auto accident victims. No-fault coverages have been extended to groups of auto accident victims previously ineligible (e.g. single-car accident victims). The shift toward no-fault compensation has caused a somewhat greater portion of the auto insurance claim dollar to go to reimbursement of economic losses in no-fault states and a lesser portion to "general damages" or intangible losses. Claimants for fault-related benefits were more often represented by attorneys than claimants for no-fault benefits. Claimants represented by attorneys did not always receive more reimbursement, and cases involving attorneys generally took much longer to settle.

WARRANTY ADMINISTRATION. IT MAKES LOTS OF DOLLARS, BUT SOMETIMES NOT MUCH SENSE

Some progress is reported in dealers' reimbursement from automobile manufacturers for warranty work, since in most cases labor charges are paid at retail rates. Present problems seem to involve prices of replacement parts. Misunderstandings between the dealer and the manufacturer occur because warranty repair procedures are not clear-cut. Proper documentation of repair by service managers, a larger profit margin for dealers, and improved communication between dealer and factory are recommended. Company audits are considered unreasonable by dealers. An advance warranty credit program has been instituted by Datsun, similar to those of Ford, General Motors (GM) and Chrysler. Ford and GM also offer large-scale dealers direct warranty communication with the factories by computer. Smaller dealers cannot afford this service. Ford's Direct Warranty Entry system facilitates payment of warranty repair orders (RO'S), but proper filling out of RO'S is still important. One service manager considers that the dealers have no recourse in warranty work reimbursement disputes except mandatory arbitration or government regulation.

HS-026 556

TRANSIT DAMAGE: TROUBLE ALONG THE WAY

Shipments of new automobiles en route to the dealer are vulnerable to accident, theft, vandalism, and careless loading and unloading. A key problem for the dealer is the lack of uniform regulations or industrywide standards specifying what is acceptable damage and what must be disclosed to the customer by the dealer or to the dealer by the manufacturer. In four states dealers must disclose any unrepaired damage, as well as repaired damage in excess of a level set by law--glass, tires and bumpers are not included. Three other states have legislation pending. Consumer protection laws help the buyer but are of no help to the dealer who receives a slightly damaged car from the manufacturer. Seriously damaged vehicles are usually destroyed, but others may be repaired for use in company service or donated to schools for use in training mechanics. Ford Motor Co. specifies that vehicles damaged in excess of $300 are not delivered to the dealer, but repaired by the manufacturer and placed in company service or wholesaled as used cars; those with less damage are sent to the dealer for repairs. In this plan, there is a lack of correlation between dollar value and extent of damage, variation in repair procedures and local labor rates, and in acceptability by consumers in different parts of the country. Transit damage is considered a minor problem by dealers in the Midwest and Western states, where railroads have high-speed runs over well-maintained track, while eastern lines move slowly over poor track in congested urban areas, and are subject to severe damage, especially vandalism and pilferage. Auto transit damage generates more claims than any other category

of freight, accounting for 28% of all loss and damage claims f railroads. Payouts totaled $85 million in 1978, when over million vehicles were carried, with an estimated 11.9% damag along the way. The rail cars used to ship automobiles are no being enclosed and manufacturers are improving protection the cars themselves. With new equipment and careful personn training, Toyota has reduced its damage rate on shipping fro 50% to 2%. Despite improvements in the past few years, caref checking by experienced personnel is recommended; deale should be aware of their legal liability in their state, and wo for better legislation.

THE NEAR-ACCIDENT. LEARN FROM YOUR MISTAKES--PLEASE

The "near-accident" caused by the driver himself should serv as a warning to him; he should analyze his driving habits to se if this is a habitual error, and then make a conscious effort t correct the fault. Typical errors illustrated include failing t look behind when making a lane change, following too closely and careless exits from parking lots.

SPARKING PLOTS [PARKING LOTS]

A list of faulty practices commonly found in parking lots is illustrated by photographs. These include driving against the traffic; parking the wrong way, too close to the next car, or taking up more than one parking space; bumping the next car with your door; occupying space reserved for the handicapped; leaving shopping carts in the parking area; cutting across the lot; speeding; backing out without looking; and parking too far over the center line. Extra alertness by drivers is urged to compensate for faulty pedestrian practices.

HOW TO AVOID GETTING RIPPED-OFF: BRAKES

To avoid excessive repair charges, it is best to know beforehand what needs to be repaired and about how much it should cost. Automotive manuals can provide illustrations of the needed parts and their locations. A reliable repair shop can often be found through word-of-mouth; the Better Business Bureau can provide information about any unusual number of complaints against a particular firm. Since a woman alone is more apt to be ripped off, a man should go along even if he knows nothing about brakes or cars. Recommendations for a good drum brake overhaul includes: new brake linings all around; new front grease seals; resurface (grind) all drums; four new (or at least rebuilt) wheel cylinders; replacement of return springs and hold-down hardware; repacking front wheel bearings; master cylinder inspection; bleed and flush hydraulic system; road test, and final brake adjustment. A good brake job for disc/drum systems should include: new disc pads and new linings; new disc hardware, new return springs and hardware; rotors resurfaced or replaced, drums turned (ground); calipers and wheel cylinders overhauled or replaced; new front grease seals; repacking front wheel bearings; master cylinder inspection; bleeding and flushing hydraulic system; road test, and final brake adjustment. Dishonest practices include repairing drums or wheel cylinders and charging for new ones, and charging a premium rate for cheap pads; charging flat-rate for repacking the wheel bearings and rotating tires when the combined time is much less when everything is already disassembled; damaging other parts of the vehicle while working on it and then recommending repairs. Knowledge of the car's condition before it goes in the shop is advised. It is best to specify riveted, rather than bonded, brake shoes. The mechanic should check the brake lines and hoses, the white plastic check-valve mounted on the master cylinder vacuum unit, and the master cylinder. Always have the drums or discs "turned" or machined when replacing linings or pads; buy "heavy duty" or premium, but not "competition-rated" linings and pads. When traveling, it is wise to go to one of the major service centers with branches nationwide where a warranty will probably be honored.

THE VISUAL PERCEPTION OF MOTION IN DEPTH

From a theoretical model of the operations of the visual system underlying the perception of motion in depth, it now appears that information concerning this motion is processed in two distinct channels, which converge on a single motion-in-depth stage of the human visual perception system. The experiments leading to the current view of how the visual system responds to a stimulus are reviewed. A "changing-size" experiment is described which involved fatiguing a particular channel of a subject's selective adaptation system in order to sort out the neural organizations involved in different perceptual tasks. The experiment was extended to measure human visual sensitivity to flow patterns, the major stimulus correlate of motion available to a pilot landing an airplane. Both changing image size and flow patterns are compelling clues to motion in depth which play a role in both monocular and binocular vision. The perception of stereoscopic motion resulting from interactions of signals from the two eyes, and of stereoscopic position, are accomplished by quite different neural mechanisms. The use of the stereoscope is described to demonstrate how the brain utilizes the geometric difference between the right and left retinal images of a solid object. Later experiments of motion perception include those on the relative velocities of the left and right retinal images of an object and experiments (technique of stereoperimetry) to demonstrate that information on position in depth and on motion in depth are processed by different channels. The selective response of neurons to movement along a particular direction in depth was demonstrated by recording the firing patterns of single neurons in the visual cortex of anesthetized cats. Field experiments, suddenly depriving jet pilots of the vision of one eye during landings, indicated that landing performance suffered little and in some cases improved. There is found to be no simple answer to the question of how the sudden loss of binocular vision affects the perception of motion in depth, because the ratio of visual sensitivities to the binocular stimulus of changing disparity and the monocular stimulus of changing size depends on the size and velocity of the object viewed, on the inspection time, and very much on the individual.

HIGHWAY ACCIDENT REPORT. ROSS AMBULANCE SERVICE, AMBULANCE OVERTURN, STATE ROUTE 116, LITTLETON, NEW HAMPSHIRE, AUGUST 22, 1978

About 3:30 p.m. on August 22, 1978, an ambulance transporting a cardiac patient to a hospital and traveling at a calculated speed of 90 to 95 mph failed to negotiate a curve on New Hampshire State Route 116 east of Littleton, New Hampshire, and rolled over. Two persons in the ambulance were killed and the driver was injured. The patient had died before the accident. The National Transportation Safety Board determines that the probable cause of this accident was loss of control of the ambulance, which had oversteer characteristics, by an unskilled driver at a high rate of speed. A contributing cause of the accident was the driver's lack of training in the operation of the ambulance at high speeds. The National Transportation Safety Board recommended to the National Hwy. Traffic Safety Administration to provide for behind-the-wheel training in high-speed driving, requiring a student to complete successfully both a written and a behind-the-wheel examination before he is licensed; to urge the States to maintain and make available the records of all licensed emergency vehicle operators; to include ambulances and other emergency vehicles in Federal Motor Vehicle Safety Standards 220, 221, and 301; and to study the feasibility of extending FMVS Standards relating to vehicle interior padding, occupant protection, and anchorage of seats and equipment to include ambulances and other emergency vehicles. It was also recommended to the General Services Administration that Federal Specification KKK-A-1822 include maintenance of handling characteristics during modification procedures, loading instructions, body structural integrity anchorages for all equipment installed, and occupant protection. It was recommended to the National Committee on Uniform Traffic Laws and Ordinances that specific criteria be used to justify an exemption from posted speed limits, including consideration of the gravity of the patient's condition, condition of the vehicle, traffic and roadway, environmental conditions, certification of the ambulance driver, and restriction of the ambulance speed to no more than 10 mph over the posted speed limit.

AN ANALYSIS OF BICYCLE ACCIDENTS IN NORTH CAROLINA: 1974-1976. PROJECT REPORT

An analysis of the current North Carolina bicycle accident problem was conducted, to initiate a continuing program of accident data retrieval and analysis for the N.C. Bicycle Program, to update previous N.C. bicycle accident studies, and to examine the utility of other existing sources of enriched bicycle-related information. A special Hwy. Safety Res. Center (HSRC) RAPID data set was developed to provide quick access to bicycle accident data from 1974 through 1976, permitting regular data comparisons. The 1974-76 data were compared with previous data (1965-68) from an earlier HSRC study; two other classes of vehicles (motorcycles and passenger cars) were also compared with bicycles to determine differences in accident patterns. The HSRC Narrative Search System was utilized to extract over 800 crash descriptions of 1976 bicycle accidents taken from the N.C. traffic accident report form; these were analyzed for information not found on the standard report. Unfortunately, these were typically so brief that many variable items could not be coded. An analysis of the N.C. Board of Transportation Merged System, combining accident and roadway characteristics for the N.C. rural primary system, gave results about geometric variables not contained on the basic accident form. For these rural accidents, many bicycle crashes were in rural areas with partial or no development and on routes with 55 mph speed limits. Many bicycle accidents occur because of the motorist's difficulty in seeing the bicyclist and his vehicle; special equipment, such as a high-rise pennant or safety flag, and a strobe light, as well as reflective clothing worn by the rider, are recommended. Educational programs for both bicyclists and motorists are suggested. The narrative description in the accident report is a convenient section for officers to mention pre-crash factors and other information helpful to the study. Municipalities should pass and enforce ordinances dealing with hazardous bicycle riding techniques. Separation of bicyclists from motor vehicles should be arranged wherever practicable, although as a viable and relatively safe mode of transportation, the bicycle should not be overregualted or overburdened with requirements.

U.S. TRANSPORTATION INCHES INTO METRIC

The steps in the process of U.S. conversion to the metric system are reviewed since the passage of the Metric Conversion Act in 1975. In spite of emphasis on voluntary conversion, there has been much opposition; a recent survey indicated that 69% of respondents opposed a national policy of mandatory metric conversion. The pharmaceutical industry was a leader in metric conversion, followed by the wine industry. Some automobiles have been manufactured under the metric system and auto repair shops have purchased metric tools. Multinational corporations are the most obvious beneficiaries of metric conversion, or "Systeme Internationale." Small firms are the most likely to lose by converting. Costs of metric conversion are estimated either as minuscule or enormous, depending upon the source of the estimate. Conversion is viewed as an opportunity for the food industry to standardize shipping containers by "modularizing." Metric conversion of hardware (thread and bolt sizes and component dimensions) is among the most difficult problems, and the strongest argument for such conversion is to make the U.S. products compatible with those of the rest of the industrial world. Government policy at present seems to be directed at leaving the initiative to those who will be most affected (i.e. industry, the states, and the public), although conversion deadlines from international transportation organizations may cause the Dept. of Transportation (DOT) to accelerate its conversion pace. Some DOT agencies are headed toward conversion; metric measurements are used in packaging and shipping hazardous material (Materials Transportation Bureau). Progres toward conversion by other agencies is briefly mentioned (Civi Aeronautics Bureau, Federal Maritime Commission, Interstat Commerce Commission). Separate sections provide a list o metric laws and practices in international trade, including a address for obtaining information about the laws in a particula country, and a brief discussion of the effect of metric conversion on packaging dimensions.

THE AMERICANIZATION OF THE SMALL CAR

The growing importance of the small car and its effect on the market is discussed by Automotive Marketing's Retail Panel. The combination of the older car population (more than 130 million pre-downsized registered vehicles) and the new lighter smaller cars will require a larger inventory of replacement parts and more expert service. Maintenance will be important, taking precedence over appearance. Problems in the new markets are considered to be, in order of importance: inventory control, 73%; government regulations, 57%; economic conditions, 46%; rapid market changes, 24%; and competition, 12%. (The figures represent percentage of responses to the question of the biggest problem in the present aftermarket.)

SMALL CAR ALREADY HAVING EFFECT ON SALES [AUTOMOTIVE PARTS]

A field report sums up the feelings of store and service managers across the country on how the small car is influencing their business. Sales of tools and aftermarket items to do-it-yourselfers are increasing. Almost 2/3 of Automotive Marketing's Retail Panel says that more smaller cars will mean more service business for their bay operations. Problems connected with small foreign cars include possible sub-standard quality in emission controls, need for frequent front-end adjustments after driving on poor roads, complicated ignition systems, and difficulty in obtaining parts. New training and equipment is needed; few mechanics understand late model compacts of any kind. This condition should correct itself in a few more years, with the mechanic understanding the import compacts better, and the foreign manufacturer making a less complicated car.

A STANDARD ON HUMAN RESPONSE TO VIBRATION--ONE OF A NEW BREED?

Human response to vibration is used as an example for consideration of the requirements of standards in the human factors field. The International Standard for general use (ISO 2631) attempts to give acceptable levels of vibration in terms of health, comfort and working efficiency; the important variables are amplitude and frequency of vibration and duration of daily exposure. Despite certain failings, the standard is an attempt to throw light on a complex environmental problem, and may have served to promote awareness by engineers of the need to consider human problems. The purpose of standardization is discussed and its original use in regulating the production of equipment and materials is differentiated from that of standards relating to people, which may be concerned primarily with the design of equipment for optimum satisfaction of users. A clear distinction should be made between standards intended to protect people from harmful conditions or minimize the risk of people being harmed, and those intended to give advice and information. In the case of human response to vibration, it is suggested that standards should relate to agreed methods of measurement and assessment, limitations to preserve health, limitations to be applied in specific situations in order to prevent the risk of accidents, and a data base for designers to work from.

NOISE TECHNOLOGY RESEARCH NEEDS AND THE RELATIVE ROLES OF THE FEDERAL GOVERNMENT AND THE PRIVATE SECTOR. PROCEEDINGS OF THE EPA NOISE TECHNOLOGY RESEARCH SYMPOSIUM, JANUARY 29-31, 1979, DALLAS, TEXAS

A comprehensive assessment was made of current needs in noise abatement technology, as well as a comprehensive review of current research, in order to present recommendations for research to fulfill unmet needs. Workshops were conducted in control of noise from machinery and construction, from surface transportation, and from aviation sources. The ability to design and develop new equipment and processes to meet reduced noise level requirements was found lacking. There was found to be a great deal of commonality of manufacturing processes and mechanisms, with potential for multiple solutions by noise abatement research. The principal sources of surface transportation noise were found to be, for the most part, common to all vehicles. Engine noise during conventional take-off and landing of aircraft is still the principal source of noise impact in the airport community. High priority was recommended for noise research efforts on diesel engines, tire and tire-roadway interactions, and on rail wheel and track interactions. Improved and validated component noise prediction methods were considered necessary in future research on airport noise reduction. The following recommendations were also made for the roles of government, universities, and industry in performing noise abatement research. The Federal government's efforts should be directed primarily toward basic research, especially long-term and high-risk research, as a basis for new technology, and toward support for demonstration programs carried out by industry; educational institutions should train personnel and perform basic research funded by government or industry; industry's efforts should be primarily directed toward implementation of noise control technology, and toward short-duration and low-risk technology applications for specific configurations.

KEYNOTE ADDRESS [TRAFFIC NOISE]

European methods of protection against noise caused by heavy traffic are reviewed. Among the approaches mentioned are methods of measuring and predicting noise levels (by formulae, by computer, or by scale model), construction of walls or earth banks, and insulation of building facades. Research in vehicle noise abatement at the source is described, principally by engine modification (moving parts, engine block, intake and exhaust, fan). The British Quiet Heavy Vehicle Project is described, and a list provided of some European centers working on vehicle and highway noise. Railway transport noise is briefly mentioned. It is concluded that a reduction of 5 dB is possible for passenger cars, and of 10 dB for heavy trucks.

ENERGY EFFICIENCY IN PASSENGER AND FREIGHT TRANSPORTATION. A COMPARATIVE STUDY OF THE SWEDISH SITUATION

Energy consumption in passenger and freight transportation in Sweden has been analyzed in terms of propulsion, manufacture and maintenance of vehicles, and construction and maintenance of the infrastructure of traffic systems. Calculations are relevant to the mid-1970's and are representative of the energy content of crude oil as imported to Sweden. The following modes are compared: passenger transport (automobiles, buses, commuter trains, subways, aircraft), and freight (trucks, railway, and coastal shipping). It is concluded that all of the present modes have advantages according to the demands made on them, and the requirements for regular use, capacity, and available freight volume or passenger flow. Conclusions about the most energy-efficient mode must be limited to specific conditions. Efforts to find the most energy-efficient transportation approach should be directed towards achieving the right balance among the various modes, and not towards discovering the "most energy-efficient" mode.

UNDERSTANDING ANTITRUST CHEMISTRY

In order to provide some insight into the function and effectiveness of the various types of proprietary compounds available for rust prevention or retardation, an explanation is given of how rust forms and what is required to stop the process. The electrochemistry of rusting (or corrosion) is explained and illustrated, followed by descriptions of the rust fighters. Petroleum and solvent-based rust preventives, applied as coatings to the metal surface, form a protective film. Rust inhibitors produce a chemical reaction which protects the metal surface. The three types of inhibitors are passivators (their mechanism not entirely understood); organic inhibitors, which form an adsorbed layer on metal surfaces; and vapor-phase inhibitors, similar to organic inhibitors except that they vaporize at ambient temperatures to form a thin, ionic film. Many paints and primers contain rust inhibitors; when properly applied beginning with metal pretreatment, they provide adequate rust prevention. Individual sections discuss recently developed (U.S.) rust-proofing systems (coatings) that resist heat welding during automobile manufacture, and a paste-like coating manufactured in the Netherlands which can be used for corrosion prevention of painted automotive surfaces. The layers of rust inhibiting materials used in a typical car body are illustrated.

WHAT'S GOOD FOR THE WORLD SHOULD BE GOOD FOR G.M. [GENERAL MOTORS' NEW COMPACT CARS]

General Motors' new front-wheel drive X-car (compact) successfully combines traditional American-car qualities (i.e. comfort, roominess, and performance) with the European and Japanese car virtues of efficiency and agility. The X-car's development took more than four years and cost almost $2.7 billion. The development evolved about a project center concept, which involved forming an engineering group composed of experts in design, manufacturing, assembly, customer service, and marketing. By eliminating redundant work by the different divisions, the center strives to keep manufacturing costs down and, at the same time, helps the divisions strengthen their separate identities. X-car models (e.g. Chevrolet Citation, Oldsmobile Omega) have more parts in common than any earlier GM lines, but divisional variations are more substantial than heretofore. Engineering both commonality and diversity into its cars reflects GM'S attention to tradeoffs between volume manufacturing efficiency and the varying demands of the marketplace. Examples of engineering innovations to increase reliability and longevity are transverse-mounted engines (reduced vibration), bolted rather than welded fenders (easier replaceability), and heavy-duty clutches in manual transmissions. With the X-car, GM has made the best use of its resources to position itself for a global challenge.

EXOTIC CARS: IN PERILOUS PURSUIT OF EXCELLENCE

The exotic car is a test bed for new ideas that major manufacturers cannot afford to offer on a mass production basis. Th exotic-car makers have pioneered the use of safety equipment often developed from race-car experience. They have been leaders in lightweight materials, have explored means of obtainin higher power from smaller engines, and have used aerodynamics to achieve high-speed stability and fuel economy. Radia tires first appeared as standard equipment on exotic cars. Thes technological achievements are not enough; exotic-car maker must operate under the same constraints of government-impose air pollution, fuel economy, and safety standards as all auto makers. Porsche and Jaguar, with relatively large volumes, hav comfortably survived regulation. For the mostly diminutive independents whose products are largely hand-crafted, the enormous research, development, and tooling costs required to mee rigid government standards have led to retrenchment or demise Only four of the smaller exotic-car makers are left to compet (Ferrari and Maserati in Italy, and Aston Martin Lagonda an Lotus in the U.K.). These companies continue to build cars fo the U.S. market because they could not expand sales elsewher to make up the loss and they regard U.S. regulations as precursors of what will exist in other countries.

AUTO REPAIR: PROBING THE DEPTHS

Apart from workmanship, time spent on the job, and qualities o material in repair, factors which account for the expense of aut repair include pressure for back-end profits, incentives to replace instead of repair, increasing competition in the structure o the repair industry, and consumer ignorance. Two determinations must be made by the car owner before having work done on his vehicle: what are the symptoms and where to take the car for repair. To avoid automobile repair fraud, a list of symptoms must be written by the car owner on the repair order, and a written estimate received and signed by him. If the car is still under warranty, or just out, it should be serviced by the dealer. In other cases, consideration should be given to a chain/department store/tire dealer offering full service. If a repair matter goes into dispute, it could be referred to a dealer arbitration board or the Better Business Bureaus third-party arbitration program. Probably the best private sector repair program is the American Automobile Assoc.'s (AAA) Authorized Repair Service, where AAA is the final arbiter in any repair dispute. Other recourse is on the state or local level. California has the best auto repair laws in the U.S.; Maryland is active in consumer protection, especially in terms of the repair industry. In other states there are laws regarding auto repair which are not particularly progressive nor assiduously enforced. The AAA offers the following recommendations for the consumer: do not hurry; get a second opinion if the problem seems less urgent than the garageman implies; do not authorize a major repair job at the mechanic's recommendation without being sure of the real need; and in case of dispute, do not panic.

VIOLENCE ON THE HIGHWAY

Across the U.S. traffic-related altercations are increasingly of a violent nature. Some incidents involve the cars as weapons; others involve fights between drivers. Rapid growth in traffic volume has been cited as a possible factor in aggravating driver violence. The FBI says tha one of the most dangerous things a police officer does is to interview a traffic violator. A psychiatric description of a violent driver is one who is tightly in control of his emotions and who has few outlets for expressing them. When he is driving a powerful car and gets into a frustrating situation or considers himself threatened by another driver, his emotions are expressed in a violent form. Many drivers may view their cars as reflections of themselves; when the car is threatened, the driver may feel personally attacked and respond with violence. It is felt that anyone is subject to this type of reaction, depending on the circumstances. Whatever the reason for a violent outburst, authorities caution that an angry response can only make matters worse. If involved in an accident, the best approach is to keep quiet if the other driver becomes overly argumentative. If the other driver threatens physical violence, it is advised to leave the scene and to call the police immediately to report the accident. If the car cannot be driven away, the advice is to get in the car, lock the door, and wait for the police. The objective is to avoid contact under all circumstances.

DRIVER'S VISIBILITY REQUIREMENTS FOR ROADWAY DELINEATION. VOL. 2. COLOR IDENTIFICATION OF YELLOW HIGHWAY PAINT AS A FUNCTION OF YELLOW/WHITE PIGMENT MIXTURE RATIO. FINAL REPORT

The yellow highway paint in current use is often not as visible as white paint under adverse lighting and weather conditions. It has lower initial brightness, darkens more rapidly with exposure, and contains lead pigment (lead chromate) which is more toxic and more expensive than white pigment (titanium dioxide). This study showed that up to 50% (by weight) of the lead pigment can be replaced by white pigment without losing yellow color identity under lighting and weather conditions where 100% yellow color is normally distinguishable. This maximum dilution which still permits reliable identification of yellow was determined by means of color judgments made by 20 subjects observing a series of paint mixture sample strips (8 ft x 4 in) from the driver's seat of a parked car at distances of 30 ft, 60 ft, and 90 ft, under both day and night lighting conditions. A cost savings of more than $1 million could be realized annually in the U.S. by diluting yellow paint with white paint so that a 50:50 pigment weight ratio is obtained. This results in very little color change, providing improved visibility, reduced darkening with age, and reduced toxicity. No change in equipment or procedures is required, and existing stocks of yellow paint can be used by dilution with white paint.

RESTORATIVE MAINTENANCE RETESTING OF 1977 MODEL YEAR PASSENGER CARS IN DENVER

Results are reported of an exhaust emission testing program in which 24 relatively new vehicles sampled in a Restorative Maintenance Program in Denver were retested approximately one year later. The vehicles were 1977 model year passenger cars certified for sale at high altitude; Chrysler, Ford, and General Motors vehicles were equally represented. Representatives of the three automakers assisted in the inspection and maintenance activities; testing was conducted by Automotive Testing Labs., Inc. Average hydrocarbon and carbon monoxide levels from vehicles which were tuned-up earlier had degraded to a point slightly worse than their original levels in as-received condition. The average nitrogen oxides level had also increased but not quite past the original value. Many vehicles had experienced maladjustment and disablements, although the owner reported that he felt his vehicle had been maintained according to the manufacturer's recommendations. The most frequent maladjustment was idle mixture, followed by ignition timing, choke settings, and disabled exhaust gas recirculation systems. Reductions in average emission levels followed the correction of the maladjustment and disablement actions to a point close to those after the prior tune-up. Modest fuel economy improvements were noted this year, probably due to the fact that the vehicles had now overcome the "green engine" effect.

EXPOSURE TO THE RISK OF AN ACCIDENT: A REVIEW OF THE LITERATURE, AND THE METHODOLOGY FOR THE CANADIAN STUDY

A 12-month survey of licensed drivers (May 1978-Apr 1979) is underway by the Road Safety Branch of Transport Canada to obtain a nationally-representative estimate of the number of miles driven by Canadian motorists. The sample of 9000 drivers being interviewed comprises residents of all the Canadian provinces except the Yukon Territory and the Northwest Territories. Driver and vehicle information is being solicited; in addition to being interviewed, the participants in the survey maintain a one-week "trip diary". Following an overview of the concept of exposure (to the risk of an accident), including the uses and needs of this type of data and a formal definition, a nonexhaustive review of the literature on exposure research is presented. The central focus is to describe the methodology which has been developed for the data collection effort. Topics include survey populations, sample design, dependent and independent variables, survey instruments, and interviewing protocol. The results of a pilot test conducted in Mar 1978 are also provided; they indicated that the methodology is both feasible and realistic, although several minor changes were incorporated into the final study design.

HYBRID OPTIMIZATION IN URBAN TRAFFIC NETWORKS. FINAL REPORT

A concept is introduced of explicitly incorporating the role of individual drivers as independent decision-makers in optimization of traffic control by the traffic authority. The Hybrid Optimization Problem (HOP) formulation provides a general theoretical framework for the study of this class of traffic control problems. In traffic engineering, the problems of system optimization, control optimization, and assignment have been studied independently of one another. The formulation of the HOP can be viewed as a unified approach which combines these problems in transportation systems. Different behavioral models for flow distribution are examined, necessary conditions for the optimal solution of the HOP are derived, and a physical interpretation of these conditions is provided. Possible directions are proposed for the development of algorithms applicable for solving large-scale HOP'S, and a procedure outlined for computing the upper and lower bounds of HOP optimal cost.

KEEP 55 ALIVE [NATIONAL SPEED LIMIT]

A National Safety Council study shows that there was a 15% decrease in fatality rates in urban areas from 1973 (when the 55 mph national speed limit was first proposed) to 1977, and a 23% decrease in rural areas, based on deaths per 100 million vehicle miles. Using the 1973 experience and accounting for increased miles traveled, 62,100 fatalities were predicted for 1977; the actual deaths in 1977 numbered 49,500. Reduced speeds accounted for 44% of the 12,600 net lives saved. A similar study in 1974 by the Council estimated that half of the reduction in deaths could be attributed to reduced speeds. It is known that the possibility of death or serious injury increases with speed. Although the number of miles driven has increased, the rate of deaths per miles driven has decreased by 19% since the 55 mph speed limit became law. The national speed limit has reduced driving speeds in general, and can be given credit for energy conservation. The 55 mph speed limit is a lifesaver, and its retention and increased enforcement offer the best means of combating the current upsurge of fatalities. In order to achieve proper enforcement, the states are entitled to more Federal money outside of Section 402 (Highway Safety Act) funds. The Federal government should also provide greater support to driver improvement programs. The states must make a firm commitment to support and enforce the 55 mph limit, and the individual motorist must do his part by complying with the law.

DEVELOPMENT AND EVALUATION OF A METHOD FOR MEASUREMENT OF DIESEL EXHAUST ODOR USING A DIESEL ODOR ANALYSIS SYSTEM (DOAS)

Research begun in 1973 was designed to assess an instrumental measurement method for diesel exhaust odor which was developed under CRC-APRAC sponsorship by Arthur D. Little, Inc. A wide variation in results from initial analysis of common samples using the Diesel Odor Analysis System was attributed mainly to lack of experience by participating laboratories. Three additional cooperative studies were subsequently conducted which evaluated individual procedural steps in sample extraction, injection, and instrument operation. A final cooperative study, serving as a review of each analysis step, showed that the analysis of common derived odorant samples could be measured within 0.3 Total Intensity of Aroma units by nine participating labs, a level of variability considered acceptable. Three participants investigated sampling system design and operating parameters through in-house studies. This work coupled with the analytical work led to a tentative recommended technique for measuring diesel exhaust odor intensity. Further work is recommended, including a cooperative study where collection systems are assembled at one site to collect samples from a common source, and a panel-instrument correlation study to reassess the relationship between Liquid Chromatography Oxygenate concentrations and human response to diesel odor intensity. Several nonparticipating labs have reported data suggesting a review of the efficiency of collection of current trap designs as a function of sample flow rate and trap temperature.

INTAKE MANIFOLD DEPOSIT ENGINE DYNAMOMETER TEST PROCEDURE. STATE-OF-THE-ART SUMMARY REPORT: 1973-1978

A four-year research effort was designed to develop an engine test procedure for evaluating the ability of gasolines to minimize deposits on the intake valves, ports, and runners, and quick-heat manifolds of gasoline engines. The initial procedure evaluated in 27 tests on the specified test fuel by 12 laboratories proved to be too mild in terms of intake valve deposit buildup. Variability among labs appeared to be unsatisfactory because of the lack of an acceptable rating procedure. Rating workshops were subsequently initiated, and a recommended rating procedure was submitted. These early results prompted an extension of the program to evaluate the effects of changes in engine and cycle parameters on test severity. Another series of 27 tests was conducted by ten labs. Results from this study led to development of the current dynamometer procedure which increased average intake valve deposits from 1.7 g/valve to 2.4 g/valve per test. To appreciate these levels of deposit weights, a study indicated that average intake valve tulip deposits ranged from 0.09 g/valve to 9.5 g/valve with 2 g/valve to 4 g/valve being common. It is believed that 2 g/valve in the 350 cu-in-displacement engine does not appreciably affect engine performance. Additional work is underway in an attempt to decrease test variability. The proposed "Induction System Rating Procedure," recommended for adoption as a Coordinating Res. Council procedure, is appended. Future testing is recommended with consideration to smaller engines, increased load factors, and possibly turbocharging, to reflect current trends.

SURVEY OF LUBRICANT INFLUENCE ON LIGHT-DUTY VEHICLE FUEL ECONOMY. FINAL REPORT

A technical information search was conducted on the subject of fuel economy improvement by use of friction-reducing lubricants. A literature search and interviews with technical personnel of 30 organizations involved or knowledgeable in the subject area were conducted. Based on the results of this survey, it is concluded that a significant fuel economy benefit can be obtained through the use of friction modifiers, and reduced-viscosity engine oils and rear axle lubricants. Friction modifiers are classifed in two categories: oil soluble chemicals or solid lubricants, such as graphite, in colloidal suspension; and "slippery" metals such as various forms of molybdenum, also in suspension. Additional improvements can probably be expected in the future. Current laboratory engine tests do not show the same fuel economy differences as the field results obtained to date. A customer survey program is recommended to document the benefit of friction-reducing oils in customer service, this information to serve as a data base for further laboratory test development. Sponsorship should be sought for a laboratory engine program which will map specific engine friction losses under actual engine operation conditions. A cooperative effort should be established to develop a suitable laboratory research technique for predicting the fuel-efficient capabilities of prospective oil candidates.

DEVELOPMENT OF RESEARCH TECHNIQUE FOR THE STUDY OF THERMAL OXIDATION STABILITY OF GEAR LUBRICANTS

During the period 1967 to 1977, research was conducted to develop a test method for laboratory estimation of the thermal oxidation stability of automotive gear oils. The results of cooperative testing of a series of samples with refinements of a test method originally devised by the Army Fuels and Lubricants Lab. (Thermal Oxidation Stability Test) are presented. Several laboratories also tried to duplicate the evaluations in glassware equipment, but the results and the availability of necessary apparatus suggested that the best approach was to use the apparatus developed by the Army. A final version of the test technique (CRC-L-60-78), which gives satisfactory repeatability and reproducibility, is appended.

1977 CRC [COORDINATING RESEARCH COUNCIL] ALTITUDE PROGRAM AUTO EXHAUST EMISSION STANDARDS AND OCTANE REQUIREMENTS]

The octane number requirement (ONR) was determined for each of 120 1977 model U.S. cars (20 cars each of 6 models) at an altitude of 5280 ft, and 24 of these cars (4 cars of each model) were then transported to sea level for ONR testing. Requirements were measured on Primary Reference fuels and two Full-Boiling Range Unleaded Reference fuels in order to determine the impact of altitude exhaust emission standards on ONR'S of altitude-calibrated cars, and to determine if the former relationship of altitude increase to decrease in ONR has changed. The evaluated data indicates that the changes made in altitude-calibrated cars to meet high-altitude emission standards do not significantly affect ONR'S at sea level when compared to sea-level cars tested at sea level. The relative rate of drop in ONR'S with increasing altitude may have decreased slightly for the 1977 model year cars as compared with 1971 and 1972 models, but the rate of drop is similar to that reported for 1967-1970 model cars and should not be considered as a major change. The detailed test program is appended.

A METHOD OF SAVING MONEY [CAR-POOLING]

In view of the new Transport Act in Britain which legalizes the carrying of paying passengers by private car owners on work or other nonprofit-making trips, and the agreement by insurance companies to relax their definitions of "carriage for hire or reward," the benefits to be derived from establishing car-sharing schemes are enumerated. Benefits to the employer include a reduced demand for parking facilities, access to larger labor market, and improved public image. Benefits to the participating employees include saving in gasoline costs for those who previously drove alone, and increased comfort and reduced cost for former mass transit users. Local and national benefits include reduced peak hour congestion on roads and on public transport, more effective use of existing roadspace and parking space, reduced fuel consumption, less pollution, and more efficient use of the public transport infrastructure. The Inst. of Transport Studies, which will administer ride-sharing schemes in large centers of employment in Britain during 1979, will benefit by obtaining data on the operation of such schemes. The main participant incentives, which are necessary for car-sharing success as experienced in the U.S. and elsewhere, are outlined and discussed. These include provision of information to workers whose schedules are compatible, legality of accepting contributions for fuel costs, freedom to use flexitime, and preferential treatment in parking areas and on the roads.

THE BODY BUILDERS [REBUILDING OF SEVERELY DAMAGED CARS]

Paradoxically, in an age of built-in obsolescence, repair work to accident-damaged vehicles is being carried out on a more extensive scale than ever before. The advance in repair techniques makes it comparatively easy today to restore car bodies that would once have been consigned to the scrap heap. Normal practice today is to mount the damaged body on a measuring jig, then to pull the damaged metal sections back into shape using hydraulic pulling equipment. The most damaged panels are replaced with new ones. An important part of the restoration technique is to pull the distorted sections back to shape in reverse order to the sequence in which they were damaged: the four suspension mountings are restored to their correct horizontal and vertical positions, the wheel geometry can then be corrected, and everything else follows. Important developments which have led to reduced repair costs include part panels, MIG welding (can be carried out from one side only and without trim removal), and paint that can be cured at any temperature. A much higher potential of repairability exists in the U.K. than ever before, and repairs can usually be carried out at extremely competitive prices. The trend is now a return to small, independent firm vs. franchises in doing body repair work, as well as more extensive repairing vs. unit replacement. The repair industry will be formed around specialists who conform to the code of practice as drawn up by the Vehicle Builders and Repairers Assoc. in conjunction with the Office of Fair Trading.

PROPANE: LOGICAL GAS ALTERNATIVE?

Information is provided to help the recreational vehicle (RV) owner make an intelligent decision on whether to convert to propane fuel or dual-fuel (gasoline/propane) use. Test results for a new Itasca mini motorhome (Winnebago) with dual-fuel capability illustrate that the use of propane vs. gasoline does reduce fuel economy and performance. The price differential between propane and gasoline currently makes the fuel economy penalty seem almost insignificant. Propane prices will undoubtedly increase, but its supply outlook is favorable compared to gasoline. Whether or not propane is practical depends primarily on its availability and price in the areas where the motor-home owner usually travels. If the decision is made to convert to propane, the choice then must be made between dual- vs. single-fuel, one of the critical factors being tank size. An RV operating on propane must have enough capacity to avoid running out of fuel. The required amount depends on individual travel habits and availability in specific areas. A single-fuel system is not practical with less than 70 or 80 gal. of propane. Single-fuel setups do have the advantage of slightly improved fuel economy and performance. With propane use, operating temperatures must be lower; adjustments must be made to the engine coolant thermostats and fans with fluid-drive clutches. Some minor work is also required on the ignition system, and addition of cool-air induction to the air cleaner is necessary. Safety is not a problem with propane use if RV owners follow basic safety procedures. The prospective propane conversion buyer must weigh the liabilities of propane use against the advantages for his own situation.

THE ROLE OF DRIVERS' VISION IN ROAD SAFETY

The literature is reviewed on the relationships between driver's vision and driving performance, and some recent progress and anticipated developments are described which give promise of filling some of the gaps in the present state of knowledge. A weak but statistically significant positive association exists between driving performance (including accident record) and the following vision tests: dynamic acuity, angular movement detection, detection of movement in depth, and to a lesser extent, static visual acuity; significant associations have not often been found for younger drivers (particularly in the case of static acuity). The practical value for driver licensing purposes of all of these associations is low; vision tests are found to be poor predictors of accidents to individual drivers. Statistically significant associations have not been generally found for a number of vision tests, including those of color vision, stereoscopic acuity, ocular muscle imbalance, and visual fields, but exceptions to this generalization may occur in specific circumstances. Further evidence is required before an assessment can be made of the relevance of night vision tests and of monocularity to driving performance. Strong positive associations between driving performance and both kinetic visual acuity and cross-dominance need to be studied further. A new rapid test of contrast sensitivity function is being evaluated in terms of driver accident record.

TRAFFIC SPEED REPORT NO. 108. INTERIM REPORT, JANUARY-MARCH, 1979 [INDIANA HIGHWAYS]

In a continuing study of vehicle speeds on Indiana highways, spot-speed observations were made of automobiles and trucks on rural Interstate, four-lane, and two-lane highways and on urban Interstate highways throughout the state during the Jan-Mar 1979 quarter. Results indicate that the average speed for all vehicles is relatively unchanged from the previous quarter. The overall average speed for passenger cars and all trucks was 58.3 mph and 57.4 mph, respectively. These speeds were 0.5 mph and 0.2 mph less, respectively, for passenger cars and trucks than speeds found in the Oct-Dec 1978 quarter.

METHODOLOGY FOR EVALUATING THE IMPACTS OF ENERGY, NATIONAL ECONOMY, AND PUBLIC POLICIES ON STATE HIGHWAY FINANCING AND PERFORMANCE. FINAL REPORT

A computer simulation model was developed to analyze and estimate the complex interactions among the critical factors influencing state highway financing, with their impact on highway performance. The model, designed to enable legislators to make informed decisions on highway financing, was extensively tested and applied to the Indiana situation. The model utilized the national energy and economic forecasts developed by Data Resources Inc. along with various assumptions regarding legislative options to project a probable range of Indiana highway performance. Results indicate that an overall deterioration in highway performance can be expected to continue in Indiana because of the enormous funds required to stabilize or improve such performance. The extent of future deterioration can be regulated by new taxing policies, revised highway performance criteria, and governmental promotion of carpooling, mass transit, and other factors that may effectively reduce future highway congestion. Options considered in this study revealed that although a general decline in highway performance can be expected, appropriate highway policy decisions can assure the sustenance of a tolerable level of highway performance well into the future.

A MULTIDISCIPLINARY TEAM STUDY OF HIGH ACCIDENT LOCATIONS. INTERIM REPORT

This research developed a multidisciplinary team approach to investigate high-accident locations in order to identify the predominant accident types and causal factors, and to suggest possible countermeasures. Four teams were organized, each consisting of an Indiana State Hwy. Commission (ISHC) central office traffic engineer, an ISHC district traffic engineer, a local traffic engineer, a human factors person, and a law enforcement officer. The data required for a team field investigation of 18 high-accident sites were developed. A manual was developed that briefly describes the goals of the multidisciplinary team investigation, prescribes the necessary professional disciplines, and outlines a procedure for field investigation. Each member individually drives all approaches to the site, reviews the data packages supplied, identifies the accident types and causal factors, and suggests possible countermeasures. After all five members return their evaluation forms and the team leader has summarized the results, the team may meet to discuss the results and reach a consensus, or the team leader may make the final determination. The multidisciplinary team approach proved to be effective in developing possible measures to improve high-accident locations in Indiana. An annotated bibliography is included.

MANY STATES RECONSIDERING LOWERED DRINKING-AGE LAWS

Nationally, since the early 1970's when the majority of states lowered their legal drinking age, there has been a 28% increase in the number of alcohol-related traffic accidents involving the under-20 driver, according to a Dept. of Transportation survey. The involvement of drinking teenagers in traffic accidents or fatalities before and after lowering the drinking age is compared in various states: in Arizona, involvement in fatal accidents doubled in 1975 over 1971; in Illinois, there was a 33% increase in traffic accident involvement in 1977 over 1973; in Connecticut, involvement in traffic accidents increased from 13% to 24% in 1975 over 1972; in Iowa, there was an immediate increase in youth fatalities in 1973; and in Michigan, there was a 119% increase in accidents involving drinking teenagers in the three years following lowering of the drinking age. Results of a recent survey of high school students conducted by the National Hwy. Traffic Safety Administration demonstrate the extent of the teenage drinking problem. By their senior year of high school, 93% of males, and 87% of females have experimented with alcohol. Half of all those in high school drink at least once a week. Forty percent report that they have at least four drinks in any one day during a given week. Half of the licensed drivers say they have driven drunk at least once; 67% feel they can drink five beers in a two-hour period and still remain within the legal limit; 28% believe they drive as well or better under the influence of alcohol. These statistics have resulted in a trend toward increasing the legal drinking age in many states in which it was recently lowered.

THE CHILD RESTRAINT PICTURE. AN INTERVIEW WITH JOHN W. MELVIN

Dr. John W. Melvin, of the Univ. of Michigan's Hwy. Safety Res. Inst. (HSRI), provides answers to questions on child restraints. The present Federal Motor Vehicle Safety Standard 213, which requires only a static test of child seats, is limited in establishing some structural deficiencies in child restraints. The standard is not totally inadequate in that it has eliminated child seats that were merely seats, and it is now being revised to include dynamic testing. It is hoped that this new standard will not eliminate seats that have proven effective in the field. The key factors in child restraint design are control of child's motion to prevent contact with vehicle interior, provision of a secure anchorage, and durability to withstand a crash. Most child restraint systems rely on the adult belt systems as their main source for attachment to the vehicle. Only 10% to 15% of children four years of age or younger presently use some form of child restraint. A one-year field study by HSRI showed the benefits of a child being restrained in terms of reduced number of contact points and incidence of contacts. The great majority of children under age 10 are not restrained in cars by either child or adult restraints. A lack of understanding of the seriousness of even minor collisions for unrestrained children, the poor human-factors design of restraints, and the costliness of some restraints are the main reasons for parents' failure to use child restraints. Pediatricians and the Federal government are becoming active in public education programs. Some of the mandatory child restraint use legislation now being proposed by some states is inadequate because of lack of information. The overall picture is that there is a low rate of child restraint use, some poorly designed restraints are in use, and some well-designed ones are not being used properly.

CLAYBROOK RESPONDS TO THE AIR BAG CRITICS

Excerpts are presented from a letter by Joan Claybrook, head of the National Hwy. Traffic Safety Administration (NHTSA), addressing concerns about air bags expressed by a few members of the House Commerce Com. NHTSA has a detailed air bag evaluation program under development as recommended by the National Transportation Board. NHTSA believes that the manufacturers, as required by design standards, have acted responsibly in fully exploring the ramifications of the use of sodium azide as a propellant for air bag systems. Since air bags are effective only in frontal collisions, they cannot be expected to offer an overall remedy. Restraint systems of any kind are minimal in side collisions; the structure and energy-absorbing materials used in the door area are the critical factors. Reports from 600 million miles of travel in cars equipped with air bags have shown the passive restraints to be highly reliable. Air bags add little weight to an automobile, particularly in comparison with many common vehicle options. The added weight of the air bags will increase fuel use by a small amount (less than 5 gal/yr/average car), but this expense will be more than offset by reduced insurance premiums and medical costs in case of crash involvement. It is not feasible to return to the "Coleman plan" for occupant restraints. Although the Dept. of Transportation's policy is to strongly encourage the use of conventional, active belts, NHTSA believes that the only feasible way of providing occupant crash protection for the majority of motorists is by automatic systems.

ENGINES AND CYCLES AIM FOR EFFICIENCY

The Dept. of Energy (DOE) awarded $57 million in grants in 1978 for development of more efficient engines and drives. Mechanical Technology, Inc., (MTI) of Latham, N.Y. has a contract to manage the program to develop an automotive Stirling engine. United Stirling of Sweden will develop and supply the engines, and AM General (subsidiary of American Motors Corp.) will be responsible for integrating the engine into U.S. vehicles. The plan is to raise the power of the baseline engine to 135 hp and efficiency to 39% by increasing peak operating temperature to 820 degrees C. The Brayton cycle gas turbine is being developed under extensive DOE grants, but many problems must be resolved before the gas turbine can compete in efficiency with conventional Otto and Diesel engines. Aircraft gas turbine design changes proposed by General Electric and Pratt and Whitney, and supported by DOE, are expected to result in an overall engine efficiency increase of 12%. Fuel injection and stratified-charge combustion engines have received no attention by DOE, although the end of the conventional gasoline engine is not in sight. Automotive companies are doing a lot of piecemeal development, but only to meet specific efficiency and emission standards. Thermo Electron Corp. (Waltham, Mass.) under DOE sponsorship, is working on the so-called bottoming-cycle diesel which promises 15% better peak efficiency. An alternative to the gas turbine is an open Brayton cycle with a reciprocating compressor and reciprocating power unit, rather than rotating elements; Glenn Warren (the Warren engine) has completed theoretical studies at MTI. DOE plans more development of the hybrid engine/electric vehicle in the future; most research today is aimed at developing batteries and electric drives that are self-sufficient for local and some extended travel. Two DOE-sponsored programs, other than those for engines, involve thermal storage media and hydraulic-mechanical split drives (Thermo Electron Corp. and Orshansky Drives Inc., respectively).

AN AUTOMOBILE NOISE ANNOYANCE PROBLEM

In response to inquiries by an automobile manufacturer who received an unusual number of complaints about noise in the drivetrain, a sequential approach was taken to differentiate among possible noise sources and their general degree of importance. Preliminary engine tests were made to discover the identity of primary noise signals and the particular units of the drivetrain responsible. After identifying the differential assembly as the origin of the annoyance, subjective and objective quantification of noise and identification of noise-radiating components and development of "fixes" (noise reduction) were pursued. Respective fixes were subjected to quantification. As few as three trained observers could make adequate subjective evaluations of product noise acceptance. The perceived and measured noise levels originating with the differential gears were a function of the gear loading (vehicle acceleration rate); it was therefore essential to achieve repeatable gear loading during testing. Major noise control means were as follows: heavy mass loading and surface damping of propeller shaft, moderate vibration damping of propeller shaft, careful placement of drive pinions relative to ring gear and proper compression of pinion shaft bearings, and careful assembly of rear suspension system to assure that vibration isolators are correctly installed and loaded to achieve design specifications. The net result was a marked decrease in customer complaints. The cost of additional materials and labor was less than 1 cent/car and less than 20 cents/car, respectively. Added to these were the costs of reliability checking and limited rejections. Ultimately, customer satisfaction achieved was gratifying in both competitive and economic terms.

SAFETY BELT USAGE. HEARINGS BEFORE THE SUBCOMMITTEE ON INVESTIGATIONS AND REVIEW, SAN JUAN, PUERTO RICO--JANUARY 4, 5, 1978; WASHINGTON, D.C.--JUNE 6, 7, 8, 1978

Testimony and material submitted for the record are presented from two separate congressional hearings on safety belt usage, one held in San Juan, Puerto Rico (the only U.S. jurisdiction to enact mandatory seat belt use legislation) and the other in Washington, D.C. Government officials, private citizens, law enforcement personnel, and representatives from public interest groups, highway safety research institutions, auto clubs, the automotive industry, the insurance industry, and the medical profession testified and/or submitted material. Submitted material includes articles, tables, charts, graphs, letters, fact sheets, biographical sketches, news releases, prepared statements, and a section of the "Federal Register" (16 Dec 1976) on proposed rulemaking concerning improvement of seat belt assemblies.

PASSIVE RESTRAINT RULE. HEARINGS BEFORE THE SUBCOMMITTEE FOR CONSUMERS, ON DEPARTMENT OF TRANSPORTATION'S JUNE 30, 1977 PASSIVE RESTRAINT RULE, SEPTEMBER 8, 9, 14, AND 21, 1977

Testimony and additional articles, letters, and statements are presented from congressional hearings on the Dept. of Transportation's motor vehicle safety rule proposed 30 Jun, 1977 which would require that automatic occupant crash protection devices be phased into the front seat positions of all new cars during model years 1982 through 1984. Air cushion restraints and passive seat belts are the primary automatic restraints in question. Government officials, private citizens, and representatives from public interest groups, highway safety research institutions, auto clubs, the automotive industry, the insurance industry, and the medical profession testified and/or submitted material.

IOWA MOTORCYCLE CRASH STUDY 1974-1976

As part of a continuous study of motorcycle crashes in Iowa (with updates every three years), statistical data are provided for the period 1974-1976. Iowa motorcycle registrations in 1976 increased 1200% over those of 1960 (11,668 in 1960 and 151,131 in 1976). This increase was characterized by a rapid rate of growth from 1964 through 1974, and a diminishing growth rate from 1975 through 1976. The motorcycle fatalities growth trend corresponded to that of registrations during the 1974-1976 period. Motorcycle registrations accounted for 6.5% of total vehicle registrations for this period, while motorcycle fatalities accounted for 9.1% of the total traffic fatalities. Multivehicle crashes in which motorcyclists were at fault usually involved violations of traffic laws. (Speeding and driving after drinking were the most frequent violations.) For the other motorists, failure to yield to the motorcyclist, drinking, and improper turns were the most frequent violations. In 1976, 20% of the fatalities were passengers on motorcycles compared to 8.5% in 1974 and 1975. There was a decrease in fatalities during the period when the helmet law was in effect, and an increase post-repeal.

TRANSPORTATION ACCIDENTS: A GUIDE TO PUBLISHED STATISTICAL SOURCES

This guide, intended for those needing detailed statistical data on transportation accidents, mainly cites serial publications, but a few special reports and studies of special interest have been included. Annotations are provided to indicate sample size and/or arrangement and detail of data. The sources are categorized as multi-modal, air, bicycle, mass transit, motor vehicle, pipeline, rail, or water.

A COMPARATIVE STUDY OF THE RIDE QUALITY OF TRACV [TRACKED RAM AIR CUSHION VEHICLE] SUSPENSION ALTERNATIVES. INTERIM REPORT

A linearized model of the pitch-heave dynamics of a Tracked Ram Air Cushion Vehicle is presented, based on aerodynamic theory which has been verified by wind tunnel and towed model experiments, The vehicle is assumed to be equipped with two controls which can be configured to provide various suspension system characteristics. The ride qualities and dynamic motions of the rigid vehicle moving over a guideway described by roughness characteristics typical of highways are examined in terms of the root mean squared (rms) values of the vertical acceleration in the foremost and rearmost seats in the passenger cabin and the gap variations at the leading and trailing edges of the vehicle. The improvement in ride qualities and dynamic behavior which can be obtained by passive and active suspension systems is examined and discussed. Optimal regulator theory is employed to design the active suspension system. The predicted rms values of the vertical acceleration in the one-third octave frequency bands are compared with the vertical International Organization for Standardization Specification. It is shown that marked improvements in the ride qualities can be obtained with either the passive or active suspension system.

EMERGENCY MEDICAL SERVICES (EMS). COORDINATION AND SYSTEMS IMPROVEMENT. ISSUE PAPER

Coordination of state emergency medical service (EMS) programs and improvement of state EMS standards for training and equipment is urged in order to reduce pre-hospital mortality and morbidity. A statewide EMS program using state, regional and community EMS advisory councils is recommended. Courses developed for the Emergency Medical Technician (EMT) include a basic training program, EMT Paramedic, First Responder Training Course, Crash Victim Extrication and Emergency Vehicle Operator Courses, Dispatcher Training Program for EMT's Refresher Training Program for EMT's, Handling Hazardous Materials and Transportation Emergencies, and a CB Monitor Training Course. Original certification of personnel and a system of recurrent evaluation and training is needed to insure continuing capability. Telephone and radio constitute the two major elements of the EMS communication system. Full implementation of "911" as the universal emergency telephone number should increase coordination among emergency service agencies. In radic telecommunication, a block of frequencies in the UHF band is allotted to the EMS system, while the National Emergency Aid Radio program promotes incident reporting by CB radio from automobiles and trucks. All ground ambulances should conform to Federal Specification KKK-A-1822A, and should also carry extrication tools, unless escorted to all accidents by a rescue vehicle specifically so equipped. The provision of emergency medical services is essentially a local or community matter, and the particulars of local operation are best determined at the community level. Model legislation for Emergency Medical Services is appended.

MOTORCYCLE HELMET USE. ISSUE PAPER, REV.

At issue is the repeal or serious weakening of motorcycle helmet laws by 27 states since the enactment of the 1976 Hwy. Safety Act. Helmet use is recommended as part of an effective motorcycle safety program which should also include rider education, improved operator licensing requirements, conspicuity enhancement, vehicle inspection, and public information activities to inform other motorists about the rights and limitations of motorcycles, and the need for sharing the road safely. The organized opposition to mandatory motorcycle helmet use is noted, especially in California. ABATE (A Brotherhood Against Totalitarian Enactments) and the American Motorcycle Assoc. are the main sources of organized opposition, which involves letter-writing campaigns, public demonstrations, and attendance and testimony at legislative hearings. Helmet effectiveness studies have shown that helmet use is 95%-100% in states with helmet legislation and 40%-60% in states with no law or a weakened helmet use law; that head injury is two times higher and fatal head injury is 3-9 times higher for nonhelmeted riders. Laws requiring helmet use by persons under 18 years of age have been relatively ineffective (40% of fatally injured riders under 18 are wearing helmets). Unhelmeted riders receive more severe head injuries, requiring longer hospitalization and more costly medical care. Voluntary use promotion is unlikely to be effective. The majority of the motoring public and about half of the motorcyclists favor helmet laws. No data indicate that increased accidents or increased injury severity result from wearing helmets. Enactment and enforcement of motorc
helmet laws for operators and passengers are considered
most effective state action to reduce motorcycle injuries
deaths. An excerpt from the Model Uniform Vehicle Coc
appended.

COMPARATIVE ANALYSIS OF ALCOHOL HIGHWAY SAFETY JUDICIAL STANDARDS ANI EXISTING PROFESSIONAL STANDARDS. VOL. 1 TECHNICAL REPORT. FINAL REPORT

Existing professional standards and model codes related to
processing of drinking-driving cases through the courts v
examined in order to determine their adequacy and appropri
ness. A technical analysis and comparison of existing stand
and codes in terms of real-world needs and problems in adj
cation of drinking-driving cases were performed by the Am
can Bar Assoc. (ABA). A 13-member study team, consis
primarily of representatives of standards-producing national
ganizations, met several times to monitor the development
the technical analysis, to assess the adequacy of existing sta
ards in view of needs, to plan and conduct a Conference
National Standards for Drinking-Driving Cases (held in Ch
go, 13-14 Oct 1978), and to prepare recommendations for fu
standard and code development. It is recommended that new
supplemental standards for drinking-driving cases should be
veloped where existing standards are silent, inadequate, inap
cable, or conflicting. Standards-producing organizations sho
examine and improve, if necessary, existing standards and co
in their area of responsibility. There should be a new, comp
hensive set of criminal justice standards specific to drunk d
ing. The ABA should provide leadership in conducting
standards-setting project. The Dept. of Justice (DOJ) and De
of Health, Education, and Welfare (DHEW) should take pri
ry responsibility for leadership. Joint DOJ, DHEW, and De
of Transportation funding should be provided. The creation c
model code or uniform act dealing specifically with drinki
driving case adjudication is deemed inappropriate at this ti

COMPARATIVE ANALYSIS OF ALCOHOL HIGHWAY SAFETY JUDICIAL STANDARDS AND EXISTING PROFESSIONAL STANDARDS. VOL. 2: ANALYSIS OF STANDARDS AND CODES. FINAL REPORT

A technical analysis and comparison of existing standards a
codes related to the processing of drinking-driving ca
through the courts in terms of real-world needs and adjudic
tion problems found that standards do not focus on particul

crimes. Relevant uniform codes and model statutes do, however, offer substantive definition for specific crimes, including drinking-driving offenses. To a great extent, the many standards on criminal justice, by their general application, do address the adjudication of drinking-driving cases. It is concluded that standards concentrate on problems commonly arising in the adjudication of all crimes; they do not as a rule address drinking-driving specifically nor do they identify or deal with problems unique to that offense despite their general applicability. The special issues which differentiate a drinking-driving case are not addressed by existing standards and codes, which do not deal adequately and appropriately with judicial processing of such cases.

STATE TRAFFIC REGULATIONS AND LEGAL ISSUES PERTAINING TO VEHICLE HAZARD WARNING LIGHTS

The current status of state laws and Federal regulations concerning vehicle hazard warning lights (sometimes called "four-way flashers") is reviewed in the context of comparable provisions of the Uniform Vehicle Code. Many states have adopted laws authorizing or requiring these lights and regulating their use, but there is a rather substantial difference in provisions of dealing with use. The most significant issue involves use of vehicle hazard warning lights on a moving vehicle. Currently, this use is prohibited for vehicles subject to Federal Motor Carrier Safety Regulations. If most vehicles can and do display four-way flashers to denote a moving vehicular hazard, it is very doubtful that the Bureau of Motor Carrier Safety regulations can effectively reserve this flashing signal to denote a stopped vehicle hazard only. Use of four-way flashers on a moving vehicle is required under certain conditions by one state, and one state toll-road authority. Such use is specifically allowed by 32 states, and another 11 do not prohibit it specifically. A number of states now require or authorize the use of four-way flashers on various kinds of moving vehicles (e.g. farm tractors, highway maintenance equipment, tow trucks). There is need for a broad-based policy decision regarding the use of vehicle hazard warning lights (uniform implementation in all jurisdictions and for all vehicles). A second issue involves the validity of all the state laws in light of Federal Motor Vehicle Safety Standards, specifically in terms of the states' overall role in regulating vehicle equipment. Congressional amendment of Section 103(d), the preemption section of the National Traffic and Motor Vehicle Safety Act, would alleviate the confusion caused by the current language.

AUTOMOTIVE APPLICATIONS OF COMPOSITE MATERIALS. FINAL REPORT

An analysis is presented of the potential use of advanced composite materials (acm's) in automotive structures, based on the relative mechanical properties and costs of these materials and mild steel. The potential weight reduction obtainable by substituting ACM for steel in various components was analyzed on a functionally equivalent basis for a wide variety of fiber composites and system geometries. ACM'S considered were resin matrix, graphite fiber, graphite fiber/glass hybrid composites, and glass fiber composites. Continous fiber glass composites can offer significant weight reduction in selected applications while potentially offering cost savings to the manufacturer. Graphite glass hybrids offer the potential for increased weight reduction but at a higher manufacturers' cost. At graphite prices of $6/lb to $10/lb, these hybrids would be competitive with steel in terms of manufacturing costs, and less expensive than either steel or fiber glass composites on a life-cycle basis. If all graphite fiber composites were used, a further weight decrease would be realized, but at a prohibitively high increase in manufacturing and life-cycle vehicle costs. A discussion is included of additional problems and issues to be resolved prior to extensive use of ACM in production vehicles: durability, damageability, repair, noise vibrations and handling, recycling, and graphite fiber release. DRUGS AND DRIVING: INFORMATION NEEDS AND RESEARCH REQUIREMENTS. FINAL REPORT

A comprehensive review and analysis of the literature on the relationship between drugs (other than alcohol alone) and highway safety was undertaken to assess the state of current knowledge, to specify information needs, and to develop research recommendations. Information is presented on historical perspectives and the structure of drug and driving research, major topics in drug and driving research, and the identification of drugs of interest. Epidemiological and experimental research to describe the involvement of drugs in motor vehicle accidents is reviewed, as well as the underlying concepts of countermeasures and their constraints. Methodologic issues, problem areas, and information needs in drug and driving research are extensively discussed. Conclusions and recommendations for near-term research are developed, and a systematic program of research suggested. Appended are tabular summaries of experimental studies of drug effects on driving-related skills (references included), a review of present knowledge about the relationship between drug levels in body fluids and their effects on human performance, and a review of the state of the art in drug analysis as it applies to highway safety. It is concluded that existing information is not sufficient to determine the extent to which drugs (alone or with alcohol) increase traffic crash risk; the way in which drugs may alter human behavior to increase that risk; the significance of experimental results demonstrating the effects of drugs on behavior; and the significance of drug concentrations in body fluids.

PROJECT K-STEER. FINAL REPORT [EVALUATION OF KANSAS SYSTEM OF DRIVER LICENSE RENEWAL]

The effect of warning drivers renewing their license in Kansas that they may be retested in the examining station was investigated. The warning was stamped on the renewal examinatio notice that along with a brief handbook (containing all th correct answers) and an eye test form is mailed every four year to each licensed driver in the state. The drivers complete th exam, have their eyes tested either by their doctor or at th station, and submit the completed exam. If they miss more tha two questions, the applicants retake the exam or they may b required to show additional support for their application, suc as taking a road test. To evaluate the effect of the warning, comparison was made of the results of two groups of renewa applicants on a closed-book retest in the station. The first grou received a letter describing the project, and a two-page questionnaire, along with their renewal materials. The second grou additionally received a warning. Although the warning greatly reduced the difference between the average number of misse at-home and those in the station, it did not improve the genera test scores, nor did it significantly differentiate between th groups on the basis of the probability of doing better or wors on the retest, nor lead to different distributions of test scores. In no case did these scores correlate with geography, age, sex, years of driving, miles driven last year, hours of driving pe day, number of licensed drivers in the household, or education level.

MODEL ICE CREAM TRUCK ORDINANCE

The Model Ice Cream Truck Ordinance (MICTO) is presented, designed to prevent child pedestrian accidents at ice cream vendor locations. This ordinance is seen as more comprehensive and stringent than the Indianapolis City-County General Ordinance No. 108 (enacted in 1971) upon which it is based. It contains a multitude of restrictions on where and how vending may take place. Graphic and verbal specifications of the mandated safety equipment are also provided to promote uniformity. A version of the model regulation was field tested in Detroit and resulted in a 77% decrease in accidents among children from a three-year average of 48.7 down to 11 in 1977. The MICTO addresses where and how a vendor may sell, required inspection, inclusion of a convex mirror, prohibition of unauthorized riders, and authorization of exemptions (i.e. trucks which do not sell to children, such as "lunch wagons").

CITIZEN'S BAND RADIO HIGHWAY SAFETY EVALUATION PROJECT. VOL. 2. FINAL REPORT

An experiment was designed to evaluate the contributions made to highway safety by the use of Citizen's Band (CB) radio by state police, using State Police Troop "D" and Zone III of the New York State Thruway, Troop "T", north-central New York State. The project demonstrated that state police use of CB radio improves response times to requests for assistance, increases the number of reports on unsafe driving acts and conditions, increases public and state police participation in reporting and responding to highway safety-related incidents, and provides for a public/state police interface. Also described are results of two opinion polls: a public opinion poll taken in Maryland (no official CB radio program) and a poll of New York State Troopers who participated in the CB project. The public opinion poll indicated a high level of acceptance for state police use of CB radios. A high level of trooper acceptance was found as well, with agreement among troopers that CB radio use helps them in performing their duties. Recommendations are presented on how the effectiveness of CB radio and related communication systems supporting the highway system can be improved. Examples of public information and education efforts are appended: announcements by the Governor, New York State Police Superintendent, and Troops "D" and "T" (in newspapers and news releases), bumper stickers, brochures and road signs. Also appended is a discussion of the training program for troopers and CB operators.

AN ANALYSIS OF MOPEDS AS A POTENTIAL SAFETY PROBLEM IN THE UNITED STATES. VOL. 1: REVIEW OF THE LITERATURE AND DATA SEARCH. FINAL REPORT

A project was designed to forecast the possible moped accident problem that may develop in the U.S. over the next five to ten years: to formulate a procedure for predicting the nature and scope of the problem; to use the procedure to predict outcomes corresponding to such input values as sales volume, usage patterns, and crash rates; and based on the output, to recommend National Hwy. Traffic Safety Administration research and safety program action. Foreign literature sources are examined to identify and describe the use of the moped in other countries and to relate this where possible to the U.S. experience. Reviewed topics include moped legislation in other countries and the U.S.; numbers of mopeds, extent of usage, and user characteristics; accident data (primarily rider and environment); collision characteristics; and the nature of injuries to accident-involved moped riders. Appended are a review of Docket 75-29, Motorized Bicycles (Mopeds); a market survey report (prepared by Management Analysis Center, Inc.) on U.S. moped sales and user characteristics; and selected tables of interest.

VEHICLE HANDLING AND STABILITY; A BIBLIOGRAPHY

This bibliography represents literature acquired since the establishment of the National Highway Traffic Safety Administration (NHTSA) concerning the handling and stability of motor vehicles. It is comprised of NHTSA contract reports, reports of other organizations concerned with highway safety, and articles from periodicals in related fields. Citations follow the format used in the monthly abstract journal "Highway Safety Literature" and are indexed by a key-word-out-of-context (KWOC) listing, author, corporate author, contract number, and report number. Documents listed may be examined in the Technical Reference Branch, NHTSA, Room 5108, 400 Seventh St., S.W., Washington, D.C. 20590. Availability is given in the individual citations.

SUBCOMPACT VEHICLE ENERGY ABSORBING STEERING COLUMN EVALUATION AND IMPROVEMENT. FINAL REPORT

Testing was conducted to analyze the interrelationships between and the effects of automobile interior surfaces on driver injury. Testing was limited to frontal impacts of subcompact vehicles. At velocities near 20 mph, variations in steering wheels, steering columns and knee restraints did not substantially affect the driver's injury severity as described by FMVSS 208. At velocities near 25 mph, these effects became evident. Steering wheels which deform easily in a mode which aligns the steering wheel rim and hub to the driver's torso result in significant reductions in the driver's chest injury severity. The tube and mandrel type steering column, designed to reduce binding due to bending forces, produced less chest injury. The passive knee restraint substantially increased driver femur forces. With no knee restraint the driver submarined under the steering wheel and instrument panel, whereas with the knee restraint, the forward translation of the driver's knees was restricted, causing the driver to rotate about the H-point into the steering wheel and windshield. This reduced head and chest injury, but contributed to neck hyperextension. Photographs illustrate various components, test methods and results. Sled and barrier test results are appended.

NATIONAL PARTS RETURN PROGRAM. VOL. 2: THE EXPANSION STUDY. FINAL REPORT

The National Parts Return Program (PRP) involves the voluntary submittal by independent automotive repair facilities of failed automotive components and failure reports to assist the NHTSA in identifying the existence of safety-related manufacturing defects in design, materials, construction, or performance of motor vehicles and motor vehicle equipment. For the feasibility study, personal visits were made to 300 new car dealers, 300 automotive parts suppliers and 100 high mileage fleets to enlist support. Various follow-up and incentive techniques were then employed to develop active participation. More than 3/4 of the dealers contacted agreed to participate, and almost 100% of the fleets and parts suppliers. During the second phase of the program, the high mileage fleets contributed most; parts suppliers and dealers contributed less, giving as explanation that they rarely saw defective parts. It is recommended that the study be continued, with non-active dealers and parts suppliers replaced by additional high mileage fleets, and that a wider variety of fleets be included, such as those who do not perform their own maintenance. Frequent telephone reminders and material incentives are suggested. Appended are association reports, the field representative information kit, field enrollment kit, certificate of participation and acknowledgement letter, and a list of new participants by region.

IMPROVED MOTORCYCLIST LICENSING AND TESTING PROJECT. ANNUAL REPORT

Some preliminary evaluations are reported of the effectiveness of three motorcyle licensing programs and remedial training with a sample of 40,874 subjects (1976, 1977, and 1978 applicants for the original motorcycle license). The driver record analyses indicated a statistically significant (13%-20%) reduction in motorcycle accident frequencies during the year after application in each of the two improved licensing programs, in comparison with the present program. Comparisons of the licensing programs by the other criterion measures revealed that the two improved programs did not differ from the present program in their impact on motorcycle and automobile convictions, automobile accidents, and total accidents and convictions. The driver record evaluation of training revealed a trend indicating that the training program was effective in reducing the incidence of motorcycle accidents during the year after application. This reduction could be due to the screening effect of the two improved programs which reduced motorcycle driving exposure and discouraged more applicants with poor motorcycle driving records from obtaining a license, and/or to the skill upgrading effect of the two improved programs; the training evaluation suggested that the screening process was the more effective. Future evaluations should study the influence of skill upgrading. Appended are data collection forms, analyses of 1977 California motorcycle accidents, and a study of the covariates selected for the analyses of covariance.

1979 SURVEY OF PUBLIC PERCEPTIONS ON HIGHWAY SAFETY. FINAL REPORT

The survey, sponsored by the National Hwy. Traffic Safety Administration as part of a systematic effort to monitor perceptions on highway safety issues, includes the following four major areas of interest: the 55 mph national speed limit, safety belts, 1984 requirements for airbags or similar passive restraint or crash protection devices, and driving after drinking. A scientifically selected national sample of 1500 licensed drivers was interviewed by telephone concerning their attitudes, knowledge, and behavior with respect to the above issues. The survey also assessed drivers' awareness of public information and education campaigns, and their perceptions of accident risk. A description of the procedures and results of the survey are given. It was found that the majority of drivers overestimate their ability to avoid accidents and seriously underestimate the actual risk of one. Seventy-five percent consider the avoidance of drinking and driving the most important measure to increase safety on highways. Only 24% report regular use of safety belts, but the majority support legislation requiring everyone to wear a belt; greatest support favored a law requiring children under age five to ride in a special safety seat (84%). Automatic safety belts would be accepted by 63%; 32% would try to disconnect them. Airbags were favored by 51% and belts by 40%. The 55 mph speed limit was favored by 77%, 75% were in favor of keeping it (a support level constant for the past three years), and 76% feel the law should be enforced with a 5 mph tolerance. Public recollection of public information messages increased in 1979 over 1978 for drinking and driving, safety belts, and the 55 mph speed limit, but drivers were unable to recall any specific message. The telephone questionnaire format is appended.

STATISTICAL ANALYSIS OF PRELIMINARY DATA FOR THE SAFE PERFORMANCE CURRICULUM DRIVING KNOWLEDGE TEST. INTERIM REPORT

A statistical analysis is presented of preliminary data for the Driving Knowledge Test, one of the intermediate measures to be used in evaluating the Safe Performance Curriculum. The test, a 56-item multiple choice test, is administered on a pre/post basis to randomly formed groups of Safe Performance Curriculum (SPC) and Pre-Driver Licensing (PDL) students. During the second project year, Control students will also be administered this instrument. The analysis includes assessment of the reliability of the knowledge test, analysis of test score distributions, comparative analyses of SPC and PDL group test performance, assessment of students' level of mastery of knowledge required for the driving task, as shown by the test, and identification of any student knowledge deficiencies. Principal findings and conclusions include: that the reliability of the test is estimated to be approximately r[illegible].80, which may be considered an adequate level of reliability for a nonstandardized achievement test; that the SPC program is superior to the PDL program in terms of driving knowledge gained by students, as measured by the test (this superiority holds true for any type of student defined by sex, socioeconomic status level, and grade-point average, as well as for subtests of the total test); and that SPC students acquire a high level of mastery of knowledge required for the driving task, as measured by the test (a mean of 48.2 on the post-test out of a possible 56). The Driving Knowledge Test and data on test scores are appended.

DEVELOPMENT OF A TEST METHODOLOGY FOR EVALUATING CRASH COMPATIBILITY AND AGGRESSIVENESS. TEST REPORT 1: 1975 HONDA CIVIC CVCC-TO-NHTSA TEST DEVICE. FINAL REPORT

Results are presented of two full-scale, head-on collisions between the NHTSA Test Device and 1975 Honda Civic CVCC two-door sedans. The test was designed to help establish a methodology for evaluating crash compatibility and aggressiveness. The Test Device is a unique, honeycomb-faced load-measuring tool which is adaptable to both moving and fixed barrier collisions. Data presented include graphical and tabular presentations of vehicle deformation, Test Device load cell data, vehicle and simulated occupant acceleration, velocity, and displacement values, dynamic displacement of string potentiometers, and restraint survival distances. Also included are tabular summaries of occupant injury criteria, exterior and interior static vehicle deformation, and restraint system loads and vehicle descriptions. Data for a 40mph fixed Test Device collision is compared to that for an "equivalent" moving Test Device collision.

NATIONAL CRASH SEVERITY STUDY STATISTICS. SPECIAL REPORT

The National Crash Severity Study (NCSS) is a major accident data collection program of the National Center for Statistics and Analysis of the National Hwy. Traffic Safety Administration. Data collection began in Jan 1977 and terminated in Mar 1979. The tabulations in this factbook represent the first 15 months of the program (Jan 1977-Mar 1978). Accidents were investigated in seven geographical areas within the continental U.S. selected so that the aggregate of the areas closely resembles the urbanization distribution of the entire country. Within each area a stratified sampling plan was used to gather detailed information on passenger cars (and their occupants) in crashes severe enough to require that the vehicles be towed from the scene. The combined investigations presented here account for 6626 crashes, 8616 towed vehicles, 14,491 vehicle occupants, and 485 fatalities. The tables and figures were generated using a computer file of the NCSS data and represent only a very broad treatment of the data. The tables are classified under the following headings: general, accident, vehicle, occupant, and crash severity (Delta V). A subject index is provided.

MAINTENANCE OF CRASH2 PROGRAM. FINAL REPORT

Work is described which was undertaken to resolve problems resulting in errors or inconsistencies in the CRASH2 program. The modifications include fixing the CDC (collision damage or deformation classification) screening test to disallow additional invalid CDC'S; fixing the BATCH option so that multiple files may be stored and run; correcting the default damage pattern for corner collisions where CDC only is specified; and adding coding to assign a default damage length of 16 in maximum to vehicles whose CDC have an E in column 6. Expenditures are reported, and recommendations for further work in maintenance of the CRASH program are given. Attached are the first and second progress reports and a computer printout illustrating the overlay approach.

HANDBOOK ON FINANCING OPTIONS FOR DIAGNOSTIC INSPECTION PROGRAMS. TECHNICAL REPORT

A major impediment to initiating motor vehicle diagnostic inspection programs is the high initial capital investment needed to establish inspection centers. At the present time, few of the wide range of public and private finance methods available are geared specifically toward motor vehicle diagnostic inspection programs. Innovative methods are described by which, in the absence of a specific funding mechanism, a state or local government planner or private entrepreneur may obtain required funds from currently available sources. The funding mechanisms are divided into two main categories, public and private financing, to coincide with the two basic administrative organizational approaches to the various inspection concepts. State and local government funding mechanisms are described, including Federal domestic assistance and state and locally generated revenues. The report also contains the spectrum of funding mechanisms, including commercial banks and capital investment firms, applicable to private for-profit and non-profit enterprises such as cooperatives and auto service clubs. Appended are a glossary of financial terms, a list of inspection agencies visited, and addresses of financing information sources.

IMPACT OF DISCONTINUING IDAHO'S PERIODIC MOTOR VEHICLE INSPECTION PROGRAM (A BEFORE AND AFTER OUTAGE RATE STUDY). TECHNICAL REPORT

The State of Idaho established (1 Jan 1968), and subsequently repealed (30 Jun 1976), a mandatory periodic (annual) motor vehicle inspection program (PMVI). The inspections were performed by state certified inspectors at private stations licensed by the state. This inspection met most vehicle-in-use standards of the National Highway Traffic Safety Administration (NHTSA). Following the discontinuance of mandatory periodic motor vehicle inspection, a study was undertaken by the Idaho Bureau of Highway Safety, under NHTSA sponsorship, to compare the mechanical condition of vehicles under a periodic inspection program to that of vehicles without such a program. To accomplish this objective, a "before and after" study was designed to assess any differences in the mechanical condition of vehicles subsequent to the abolition of Idaho's mandatory inspection law. Outage rates were lower during the tenure of PMVI for the brake systems of older, high mileage vehicles (4 years old, 40,000 miles or more), for steering, suspension, and powertrain subsystems for cars of all ages and mileage. Only subsystems which were visible, accessible, and easily maintained (brake lights, turn indicators, and window glass) showed no difference in outages, pre- and post-repeal of PMVI. It was concluded that Idaho's vehicles were in better condition under their PMVI program than they are now without such a program, as measured by subsystem outage rates.

IMPACT OF AUTOMOTIVE FUEL ECONOMY STANDARDS ON COMPETITION IN THE AUTOMOTIVE INDUSTRY. VOL. 2, FINAL TECHNICAL REPORT

Means were developed for assessing competition among domestic and foreign automotive corporations by which impacts on competition in response to Federally mandated fuel economy standards are identified and analyzed. In the areas of engineering/design and product planning, relatively modest competitive impacts are projected, although manufacturers in the smaller car segments appear somewhat vulnerable near-term to image erosion caused by a reduction in available design alternatives. More severe risks to the stability of the industry's competitive structure are foreseen in the area of product pricing and overall marketing strategy. These risks are due to incentives inherent in the corporate average fuel economy standards for cross-subsidization in the marketing of different size classes. Incentives for pursuing alternative marketing strategies are analyzed in the context of the Wharton E.F.A. (Economic Forecasting Associates) automobile demand forecasting model. The analysis suggests that incentives do exist for relatively modest adjustments in pricing mix. Since the relative attractiveness of such strategies declines rapidly as they are pursued more intensively, the major threat to competitive equilibrium from this source is the extent to which the automakers fall short of their timetables of technological improvements to achieve the standards.

IMPACT RESISTANCE OF NON-FERROUS PASSENGER CAR WHEELS--MODIFICATION NUMBER 2. FINAL REPORT

Two impact tests were conducted on ferrous wheels using the proposed procedure ISO/TC22/SC19/WG3-N15 to compare the nature and extent of failures, to assess the significance of material strength and ductility, and to determine the adaptability of the tests to a Federal Standard. The test machine, which was designed and fabricated for the original contract, was modified. Eight aluminum wheels were procured, of which two from Cragar were tested and passed. The six remaining wheels and test machines were shipped to the National Hwy. Traffic Safety Administration. Appended are photographs of the test machine and wheel impacts, and an outline of the test procedure.

A COMPARISON OF ALCOHOL INVOLVEMENT IN PEDESTRIANS AND PEDESTRIAN CASUALTIES. EXECUTIVE SUMMARY

A study was undertaken to determine the frequency of alcohol involvement in adult (14 years) pedestrian fatalities and injuries; to determine if alcohol was overrepresented; to determine the causal role of alcohol; and to suggest countermeasures. Pedestrian fatalities were sampled through the New Orleans, La., Coroner; non-fatal pedestrian victims were sampled through a large New Orleans hospital; and crash and control data were gathered via follow-up interviews, roadside interviews and police files. Results showed that 50% of the pedestrian fatal and non-fatal victims had been drinking. Blood Alcohol Concentrations (BAC'S) were extremely high. Approximately 50% of those who had been drinking had BAC'S of .20% or higher. Victims were compared to three distinct control groups. The most conservative group (age and sex matched at the accident site) showed relative risk of an accident increasing dramatically at BAC'S of .20% or more. The least conservative (Random group) showed relative risk increasing dramatically at BAC'S of .10% or more. Alcohol involved pedestrians were more often middle aged males, struck at night or on weekends, who exhibited a variety of social and personal problems. "Dart and Dash," "Ped Strikes Vehicle" and "Not Classifiable" accident types were common. Legal, educational, engineering and rehabilitation countermeasures are discussed.

RSV TEST MONITORING AND DATA PUBLICATION--RESULTS OF EUROPEAN PERFORMANCE AND HANDLING TESTS ON THE CALSPAN RSV [RESEARCH SAFETY VEHICLE]. FINAL REPORT

Performance and handling tests on the Calspan Research Safety Vehicle (RSV) were performed in Italy by the Istituto Sperimentale Auto e Motori (ISAM) and in West Germany by Volkswagenwerk AG, Wolfsburg. The ISAM tests evaluated the Calspan RSV in the areas of fuel economy, vehicle response, braking and handling, and driver environment. The Volkswagen tests evaluated the Calspan RSV in the areas of braking, steering, handling, and overturning immunity. Since the ISAM tests are unlike any previously used to evaluate American vehicles, the Calspan RSV results are compared to those of ten European cars which had undergone identical tests. The Volkswagen test procedures were identical to those specified in the Research Safety Vehicle program. The Calspan RSV results are compared to the RSV specifications for these tests. The RSV exhibited generally lower performance than the European cars in tests of engine performance (power at the wheels, maximum speed, speed track performance, and acceleration and pickup), although the RSV met specification requirements related to passing times. Fuel consumption of the RSV compared favorably with that of European cars, and the braking capability of the RSV was better than any of the European cars. The Calspan RSV met all of the specifications in the Volkswagen tests except those in the slalom tests. Appended are individual test data from the ISAM test program and the tests conducted by Volkswagen AG, as well as a summary of test results.

RSV TEST MONITORING AND DATA PUBLICATION - RENAULT R20TS-TO-CALSPAN RSV [RESEARCH SAFETY VEHICLE], 75 DEGREE RIGHT SIDE IMPACT, AT RENAULT. FINAL REPORT

The results are reported of a 75 degree right side impact collision between a Renault R20TS and the Calspan Research Safety Vehicle (RSV) No. 4. The Calspan RSV, the stationary target vehicle, was struck in the right side by the Renault bullet vehicle. The test, which was conducted by Renault, evaluated the structural integrity and dynamic response of the Calspan RSV, and the dynamic response of its three occupant dummies. Appended are the data plots for vehicles and dummies, a summary of test results, and the following conclusions. All three dummies in the Calspan RSV were within the allowable FMVSS 208 head injury criteria. The left front and right rear dummies met the FMVSS criteria for chest resultant acceleration, the right front dummy did not. The reinforced structure of the RSV, together with ample soft door padding minimizes pelvic injury indicators. Stiff padding at the tops of the doors of the RSV resulted in no observable improvement as regards the thorax. Padding the windshield pillars, center pillars, roof sills, and rear pillars limited the maximum acceleration recorded during an impact of the head.

RSV TEST MONITORING AND DATA PUBLICATION - RENAULT R20TS-TO-CALSPAN RSV [RESEARCH SAFETY VEHICLE]., 75 DEGREE LEFT SIDE IMPACT, AT PEUGEOT. FINAL REPORT.

The results are reported of a 75 degree left side impact collision test between a Renault R20TS and the Calspan Research Safety Vehicle (RSV) No. 4. The Calspan RSV, the stationary target vehicle, was struck in the left side by the Renault bullet vehicle. The test, conducted by Automobiles Peugeot in France, evaluated the structural integrity and dynamic response of the Calspan RSV, and the dynamic response of its three dummy occupants. The side door intrusion into the passenger compartment was limited to 3.8 inches maximum at the driver door, and all occupant responses met established human survival specifications. Data plots for vehicles and dummies, and a summary of significant test results and conclusions are appended.

POLICE TRAFFIC RADAR: IS IT RELIABLE?

Recent developments in police traffic radar are described and activities in performance standards and training programs by the National Hwy. Traffic Safety Administration are discussed. Results of special tests are reported on police traffic radar equipment which was questioned in a Florida judicial hearing. The researchers were concerned with the susceptibility of the radar devices to interference from citizens band and police radios, and from equipment in police vehicles (ignition, alternator, and air-conditioning and heater fans). Also examined were such phenomena as patrol speed shadowing, target speed bumping or batching, and possible errors due to panning, scanning, interpretation, and automatic lock-on feature. The results indicate that police radar is reliable when carefully installed and properly operated. It is recommended that states develop uniform standards, guidelines, and procedures for operator training and certification; equipment purchase, maintenance, testing, and certification; operating practices; and periodic recertification of equipment and operators. Included is an interim report by the National Bureau of Standards Law Enforcement Standards Lab., which provides results of a series of laboratory and field tests to evaluate the performance of six specific speed-measuring radar units.

RESEARCH SAFETY VEHICLE (RSV) CRASH TEST REPORT, TEST NO. 3054-1: 41 MPH FLAT BARRIER FRONTAL IMPACT. FINAL REPORT

The results are reported of a 41 mph frontal flat barrier crash test of the Calspan Research Safety Vehicle (RSV) No. 9. Two calibrated 50th percentile Part 572 instrumented anthropomorphic dummies were placed in the driver and front passenger positions in the car. The occupant automatic restraint system consisted of an air bag mounted in the steering wheel hub for the driver, and an air belt for the passenger. These were supplemented by knee impact padding for each occupant. Due to the driver and front passenger exceeding some aspect of the FMVSS 208 Injury Criteria, the results of this test in terms of human survival were unsatisfactory. In spite of some unexpected failures of the right front door and hood latches which occurred during the crash test, the occupant compartment intrusion was not excessive, although the compartment's relatively high accelerations presented difficult conditions for satisfactory restraint performance. Appended are plots for vehicle and dummy data, documentary photographs, occupant restraint firing data, pre- and post-test dummy calibrations, vehicle modifications, and test summary. Also appended are a pre-test wheel study, and a discussion by M. Fitzpatrick of test vehicle modifications.

RADIATORS
REPAIR OF ALUMINUM HEAT EXCHANGERS [AUTOMOBILE RADIATORS, AIR-CONDITIONER COILS AND MANIFOLDS, HEATER CORES, AND OIL COOLERS]
HS-026 508

RADIO
CITIZEN'S BAND RADIO HIGHWAY SAFETY EVALUATION PROJECT. VOL. 2. FINAL REPORT
HS-804 833

RAM
A COMPARATIVE STUDY OF THE RIDE QUALITY OF TRACV [TRACKED RAM AIR CUSHION VEHICLE] SUSPENSION ALTERNATIVES. INTERIM REPORT
HS-026 628

RANDOM
AN EVALUATION OF OHIO'S RANDOM MOTOR VEHICLE INSPECTION PROGRAM
HS-026 488

RATE
DIESEL INJECTION RATE CAN MINIMIZE EMISSIONS, MAXIMIZE ECONOMY
HS-026 534
HOW DOES COMBUSTION RATE AFFECT NOX [NITROGEN OXIDES] EMISSIONS?
HS-026 532
IMPACT OF DISCONTINUING IDAHO'S PERIODIC MOTOR VEHICLE INSPECTION PROGRAM (A BEFORE AND AFTER OUTAGE RATE STUDY). TECHNICAL REPORT
HS-805 243

RATES
GETAWAY FLOW RATES FOR FREEWAY INCIDENT AND GEOMETRIC BOTTLENECKS
HS-026 435

RATIO
DRIVER'S VISIBILITY REQUIREMENTS FOR ROADWAY DELINEATION. VOL. 2. COLOR IDENTIFICATION OF YELLOW HIGHWAY PAINT AS A FUNCTION OF YELLOW/WHITE PIGMENT MIXTURE RATIO. FINAL REPORT
HS-026 602

REAR
BASIC RESEARCH ON REAR-END COLLISIONS
HS-026 482

REBUILDING
THE BODY BUILDERS [REBUILDING OF SEVERELY DAMAGED CARS]
HS-026 613

RECONSIDERING
MANY STATES RECONSIDERING LOWERED DRINKING-AGE LAWS
HS-026 619

RECREATIONAL
WHAT YOU SHOULD KNOW ABOUT AUXILIARY TANKS [RECREATIONAL VEHICLES]
HS-026 483

RECYCLING
AN INFORMAL STUDY OF TRANSIT BUS TIRE PROCUREMENT AND RECYCLING IN MICHIGAN
HS-026 440

REDUCED
USER GUIDELINES FOR REDUCED VISIBILITY GUIDANCE SYSTEM DESIGN. EXECUTIVE SUMMARY
HS-026 518

REGULATIONS
STATE TRAFFIC REGULATIONS AND LEGAL ISSUES PERTAINING TO VEHICLE HAZARD WARNING LIGHTS
HS-804 595

REGULATORS
TARGET: HIGHWAY RISKS. 2. THE GOVERNMENT REGULATORS
HS-026 454

REGULATORY
COORDINATING TRANSPORTATION SERVICES FOR THE ELDERLY AND HANDICAPPED. STATUTORY AND REGULATORY ANALYSIS OF INCENTIVES AND BARRIERS TO COORDINATING TRANSPORTATION SERVICES FOR THE ELDERLY AND HANDICAPPED. FINAL REPORT
HS-026 428

REINFORCED
DESIGN AND FABRICATION OF AUTOMOTIVE COMPONENTS IN GRAPHITE FIBER REINFORCED COMPOSITES
HS-026 451

GRAPHITE-REINFORCED-PLASTIC PASSENGER CAR FRAME
HS-026 450

RELATIONSHIP
THE RELATIONSHIP BETWEEN ENGINE OIL VISCOSITY AND ENGINE PERFORMANCE--PT. 4
HS-026 509

RELATIVE
NOISE TECHNOLOGY RESEARCH NEEDS AND THE RELATIVE ROLES OF THE FEDERAL GOVERNMENT AND THE PRIVATE SECTOR. PROCEEDINGS OF THE EPA NOISE TECHNOLOGY RESEARCH SYMPOSIUM, JANUARY 29-31, 1979, DALLAS, TEXAS
HS-026 567

RELEVANCE
THE USE OF ALTERNATIVE FUELS IN HIGHWAY VEHICLES--THE RELEVANCE OF U.S. ENERGY FLOWS
HS-026 455

RELIABLE
DESIGNING RELIABLE SOFTWARE FOR AUTOMOTIVE APPLICATIONS
HS-026 466

POLICE TRAFFIC RADAR: IS IT RELIABLE?
HS-805 254

RENAULT
RSV TEST MONITORING AND DATA PUBLICATION - RENAULT R20TS-TO-CALSPAN RSV [RESEARCH SAFETY VEHICLE], 75 DEGREE RIGHT SIDE IMPACT, AT RENAULT. FINAL REPORT
HS-805 251

RSV TEST MONITORING AND DATA PUBLICATION - RENAULT R20TS-TO-CALSPAN RSV [RESEARCH SAFETY VEHICLE]., 75 DEGREE LEFT SIDE IMPACT, AT PEUGEOT. FINAL REPORT.
HS-805 252

RENEWAL
PROJECT K-STEER. FINAL REPORT [EVALUATION OF KANSAS SYSTEM OF DRIVER LICENSE RENEWAL]
HS-804 790

REPAIR
AUTO REPAIR: PROBING THE DEPTHS
HS-026 600

REPAIR OF ALUMINUM HEAT EXCHANGERS [AUTOMOBILE RADIATORS, AIR-CONDITIONER COILS AND MANIFOLDS, HEATER CORES, AND OIL COOLERS]
HS-026 508

REPLACED
THE DAMAGED WHEEL SHOULD BE REPLACED
HS-026 499

REQUIREMENTS
DRIVER'S VISIBILITY REQUIREMENTS FOR ROADWAY DELINEATION. VOL. 2. COLOR IDENTIFICATION OF YELLOW HIGHWAY PAINT AS A FUNCTION OF YELLOW/WHITE PIGMENT MIXTURE RATIO. FINAL REPORT
HS-026 602

DRUGS AND DRIVING: INFORMATION NEEDS AND RESEARCH REQUIREMENTS. FINAL REPORT
HS-804 774

1977 CRC [COORDINATING RESEARCH COUNCIL] ALTITUDE PROGRAM AUTO EXHAUST EMISSION STANDARDS AND OCTANE REQUIREMENTS]
HS-026 611

RESEARCH
AUTOMOBILE INJURIES AND COMPENSATION: THE AIRAC [ALL-INDUSTRY RESEARCH ADVISORY COMMITTEE] STUDY
HS-026 554

BASIC RESEARCH ON REAR-END COLLISIONS
HS-026 482

DEVELOPMENT OF RESEARCH TECHNIQUE FOR THE STUDY OF THERMAL OXIDATION STABILITY OF GEAR LUBRICANTS
HS-026 610

DRUGS AND DRIVING: INFORMATION NEEDS AND RESEARCH REQUIREMENTS. FINAL REPORT
HS-804 774

NOISE TECHNOLOGY RESEARCH NEEDS AND THE RELATIVE ROLES OF THE FEDERAL GOVERNMENT AND THE PRIVATE SECTOR. PROCEEDINGS OF THE EPA NOISE TECHNOLOGY RESEARCH SYMPOSIUM, JANUARY 29-31, 1979, DALLAS, TEXAS
HS-026 567

OPTIMIZATION OF DIESEL COMBUSTION RESEARCH
HS-026 431

RESEARCH SAFETY VEHICLE (RSV) CRASH TEST REPORT, TEST NO. 3054-1: 41 MPH FLAT BARRIER FRONTAL IMPACT. FINAL REPORT
HS-805 262

RSV TEST MONITORING AND DATA PUBLICATION - RENAULT R20TS-TO-CALSPAN RSV [RESEARCH SAFETY VEHICLE], 75 DEGREE RIGHT SIDE IMPACT, AT RENAULT. FINAL REPORT
HS-805 251

RSV TEST MONITORING AND DATA PUBLICATION - RENAULT R20TS-TO-CALSPAN RSV [RESEARCH SAFETY VEHICLE]., 75 DEGREE LEFT SIDE IMPACT, AT PEUGEOT. FINAL REPORT.
HS-805 252

RSV TEST MONITORING AND DATA PUBLICATION--RESULTS OF EUROPEAN PERFORMANCE AND HANDLING TESTS ON THE CALSPAN RSV [RESEARCH SAFETY VEHICLE]. FINAL REPORT
HS-805 250

THE APPLICATION OF VISIBILITY RESEARCH TO ROADS AND HIGHWAYS
HS-026 437

1977 CRC [COORDINATING RESEARCH COUNCIL] ALTITUDE PROGRAM AUTO EXHAUST EMISSION STANDARDS AND OCTANE REQUIREMENTS]
HS-026 611

RESISTANCE

IMPACT RESISTANCE OF NON-FERROUS PASSENGER CAR WHEELS--MODIFICATION NUMBER 2. FINAL REPORT
HS-805 247

RESPONDS

CLAYBROOK RESPONDS TO THE AIR BAG CRITICS
HS-026 621

RESPONSE

A STANDARD ON HUMAN RESPONSE TO VIBRATION--ONE OF A NEW BREED?
HS-026 566

ROAD TEXTURE INDUCED EXTERNAL TIRE NOISE. EMPIRICAL FREQUENCY RESPONSE FUNCTION FOR TIRES
HS-026 459

RESTORATIVE

RESTORATIVE MAINTENANCE RETESTING OF 1977 MODEL YEAR PASSENGER CARS IN DENVER
HS-026 603

RESTRAINT

PASSIVE RESTRAINT RULE. HEARINGS BEFORE THE SUBCOMMITTEE FOR CONSUMERS, ON DEPARTMENT OF TRANSPORTATION'S JUNE 30, 1977 PASSIVE RESTRAINT RULE, SEPTEMBER 8, 9, 14, AND 21, 1977
HS-026 625

THE CHILD RESTRAINT PICTURE. AN INTERVIEW WITH JOHN W. MELVIN
HS-026 620

RESTRAINTS

CHILD AND INFANT RESTRAINTS; A SUBJECT BIBLIOGRAPHY
HS-804 729

RESTRICTIONS

GOOD TO THE LAST DROP [IMPACT OF RESTRICTIONS ON GASOLINE USE ON THE AUTO SERVICE INDUSTRY]
HS-026 521

RESULTS

RSV TEST MONITORING AND DATA PUBLICATION--RESULTS OF EUROPEAN PERFORMANCE AND HANDLING TESTS ON THE CALSPAN RSV [RESEARCH SAFETY VEHICLE]. FINAL REPORT
HS-805 250

RETARDANT

IGNITION CHARACTERISTICS OF FLAME RETARDANT FABRICS
HS-026 519

RETESTING

RESTORATIVE MAINTENANCE RETESTING OF 1977 MODEL YEAR PASSENGER CARS IN DENVER
HS-026 603

RETURN

NATIONAL PARTS RETURN PROGRAM. VOL. 2: THE EXPANSION STUDY. FINAL REPORT
HS-805 145

THE NATIONAL PARTS RETURN PROGRAM. VOL. 3: PRP NEWS AND PROGRAM INPUTS. FINAL REPORT
HS-805 146

REVIEW

AN ANALYSIS OF MOPEDS AS A POTENTIAL SAFETY PROBLEM IN THE UNITED STATES. VOL. 1: REVIEW OF THE LITERATURE AND DATA SEARCH. FINAL REPORT
HS-804 854

EXPOSURE TO THE RISK OF AN ACCIDENT: A REVIEW OF THE LITERATURE, AND THE METHODOLOGY FOR THE CANADIAN STUDY
HS-026 604

SAFETY BELT USAGE. HEARINGS BEFORE THE SUBCOMMITTEE ON INVESTIGATIONS AND REVIEW, SAN JUAN, PUERTO RICO--JANUARY 4, 5, 1978; WASHINGTON, D.C.--JUNE 6, 7, 8, 1978
HS-026 624

VISCOSITY AND FLOW PROPERTIES OF MULTIGRADE ENGINE OILS--A REVIEW OF AN INTERNATIONAL COLLOQUIUM
HS-026 511

RIDE

A COMPARATIVE STUDY OF THE RIDE QUALITY OF TRACV [TRACKED RAM AIR CUSHION VEHICLE] SUSPENSION ALTERNATIVES. INTERIM REPORT
HS-026 628

RIDER

ISN'T IT TIME? [MOTORCYCLE RIDER EDUCATION]
HS-026 551

RIG

A STUDY OF LUBRICATING OIL PERFORMANCE IN A JOURNAL BEARING RIG
HS-026 516

RIGHT

RSV TEST MONITORING AND DATA PUBLICATION - RENAULT R20TS-TO-CALSPAN RSV [RESEARCH SAFETY VEHICLE], 75 DEGREE RIGHT SIDE IMPACT, AT RENAULT. FINAL REPORT
HS-805 251

RIPPED

HOW TO AVOID GETTING RIPPED-OFF: BRAKES
HS-026 559

RIPPLE

SMOOTH, RIPPLE-FREE PLASTIC PANELS [AUTOMOBILE BODIES]
HS-026 502

RISK

EXPOSURE TO THE RISK OF AN ACCIDENT: A REVIEW OF THE LITERATURE, AND THE METHODOLOGY FOR THE CANADIAN STUDY
HS-026 604

RISKS

NOTICE

The March and April issues of Highway Safety Literature are being issued before the February one. This is due to a delay caused by changing one of the contractors and computers used in processing the journal. We expect that the February issue will be available shortly, and that future issues will appear in chronological order.

TD 8.10:

NOTICE

Highway Safety Literature is a monthly publication of the National Highway Traffic Safet Administration (NHTSA). It is divided into the following sections: Abstract Citations, containin bibliographical information and abstracts; and an Index to Abstracts, including a keyword-out-of context (KWOC) list of words in the title, followed by the full title and HS number (our accessio number); an Author Index; a Corporate Author Index; a Contract Number Index; and a Report Number Index. In those months when information on contracts recently awarded is available, a section entitled Contracts Awarded is added at the back.

Abstracts appearing in **Highway Safety Literature** represent documents acquired by the Technical Reference Division, NHTSA. Documents related to the mission of NHTSA may be sent to the Editor at the address below for inclusion in the collection and abstracting in this publication. Please indicate availability source and price for each document.

Note: Publication of articles or abstracts in Highway Safety Literature is intended only for information. Views expressed are those of the authors and not necessarily those of the Administration. Reference to brand names, equipment, models or companies does not imply endorsement by NHTSA or the U.S. Department of Transportation.

Comments on the articles appearing in **Highway Satety Literature** may be addressed to

Editor
Highway Safety Literature
Technical Reference Division
National Highway Traffic Safety Administration
400 7th St. SW
Washington, D.C. 20590

AVAILABILITY OF DOCUMENTS

Documents listed in *Highway Safety Literature* are not available from the National Highway Traffic Safety Administration unless so specified. They must be ordered from the sources indicated on the citations, usually at cost. Ordering information for the most common sources is given below.

NTIS: National Technical Information Service, Springfield, Va. 22161. **Order by title and accession number: PB, AD, or HS.** When no PB number is given for NHTSA Technical Reports, order by prefacing the HS number with DOT, i.e. DOT-HS-000 000.

GPO: Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. **Give corporate author, title, personal author, and catalog or stock number.**

Reference copy only: Documents may be examined at the NHTSA Technical Reference Division or borrowed on inter-library loan through your local library.

See publication: Articles in journals, papers in proceedings, or chapters in books are found in the publication cited. These publications may be in libraries or purchased from publishers or dealers.

SAE: Society of Automotive Engineers, Dept. HSL, 400 Commonwealth Drive, Warrendale, Pa. 15096. Order by title and SAE report number.

TRB: Transportation Research Board, National Academy of Sciences, 2101 Constitution Ave., N.W., Washington, D.C. 20418.

Corporate author: Inquiries should be addressed to the organization listed in the individual citation.

ABSTRACT CITATIONS

SAMPLE ENTRIES

FORMAT OF ENTRIES IN HIGHWAY SAFETY LITERATURE

NHTSA accession number	HS-013 124
Title of document	**MAXIMUM BRAKE PEDAL FORCES PRODUCED BY MALE AND FEMALE DRIVERS**
Abstract	The object of this research was to obtain data concerning the maximum amount of brake pedal force that automobile drivers were able to sustain over a period of ten seconds. Subjects were told to apply the brakes in the test car as they would in a panic stop, and to exert as much force as possible on the pedal over the entire ten second test period. A total of 84 subjects were tested, including 42 males and 42 females. The results indicated that there is a wide distribution of values which characterizes the pedal force that the subjects were able to generate. Male subjects produced generally higher forces than did females. Over half the women tested were unable to exert more than 150 lbs. of force with either foot alone, but when both feet were applied to the pedal, force levels rose significantly.

NHTSA accession number	HS-018 924
Title of document	**NATURAL FREQUENCIES OF THE BIAS TIRE**
Abstract	The lowest natural frequencies of a bias tire under inflation pressure are deduced by assuming the bias tire as a composite structure of a bias-laminated, toroidal membrane shell and rigorously taking three displacement components into consideration. The point collocation method is used to solve a derived system of differential equations with variable coefficients. It is found that the lowest natural frequencies calculated for two kinds of bias tire agree well with the corresponding experimental results in a wide range of inflation pressures. Results of the approximate analysis show that the influences of the in-plane inertia forces on natural frequency may be considered small, but the influences of in-plane displacements are large, particularly on the natural frequency of the tire under low inflation pressure.

TRAFFIC ANALYSIS ANNUAL REPORT, CALENDAR YEAR 1978 [DISTRICT OF COLUMBIA]

Traffic statistics are tabulated for all traffic accidents and fatalities within the District of Columbia in 1978 which were investigated by the Metropolitan Police Dept. and the Park Police Service. Previous years' statistics are presented in some tables to indicate trends. Data are given on accident locale (police district), day of week, time of day, road condition, visibility, driver characteristics, climate, seat belt use, vehicle action, lighting, vehicle characteristics, persons injured, bicycle involvement, comparisons with other cities, societal costs, pedestrian involvement, persons killed, alcohol and drug involvement, traffic citations, fines, accident countermeasure programs, and sources of traffic safety materials. For 1978 in the District of Columbia, there were 49 fatal and 2 multiple fatal accidents, 51 fatalities, 7157 injury accidents, 10,199 persons injured, 1259 pedestrian accidents, 1170 pedestrians injured, and 16,182 property damage accidents. Compared to 1977, there were more total accidents and pedestrians injured, but fewer motorist and pedestrian deaths, and fewer injury accidents and motorists injured.

HOW DOES TRAFFIC SPEED AFFECT URBAN FUEL CONSUMPTION?

A relationship between fuel consumption (gal/mi) and trip time, well-established and widely reported in the literature, is preferable on theoretical grounds and provides a superior fit to a wide variety of fuel consumption data, than a relationship presented by P. D. Christopherson and G. G. Olafson (ITE Journal v48 n11 (Nov 1978). The latter relationship (Equation 1) may be written as E equals 3.59 plus 0.40V, where E is the fuel economy of the composite vehicle simulated, in mi/gal, when traveling in traffic with an average speed of V mi/hr. The preferred relationship (Equation 2) is expressed as F equals A plus BT, or 1/E equals A plus B/V, where F is fuel consumption (gal/mi), T is average trip time per unit distance (hr/mi), E equals 1/F is fuel economy (mi/gal), and V equals 1/T is average trip speed (mph), where V is less than or approximately 35 mph. The parameter A is the fuel required to overcome rolling resistance; the parameter B is related to the idle fuel flow rate. Since Equation 1 has no physical interpretation, it necessarily yields increasingly inaccurate results as increasing traffic congestion produces lower travel speeds. Equation 2 relates to the physics of the automobile, yields meaningful results as congestion increases, and fits well a wide variety of data (including the data in the Christopherson and Olafson report which was generated by simulating various traffic networks).

COMPUTERIZED CARS. ON-BOARD MICROPROCESSORS SPARK A REVOLUTION IN AUTOMOBILE ENGINEERING

The prime impetus for U.S. development of on-board automobile microcomputers was the Federal emission regulations for the 1980's. Automakers are using a microcomputer air/fuel regulator system in combination with a three-way catalytic converter to meet emission goals. Microcomputers are also being used for such other tasks as engine control. Ford, in its 1978 Lincoln Versailles, introduced its Electronic Engine Control (EEC-I) System which calculates ignition timing and flow rates for exhaust gas recirculation, and Ford has since introduced an updated system (EEC-II) that performs more tasks. Although General Motors has been using its Computer-Controlled Catalytic Converter (C-4) system only for emission control, GM'S 1980 X-body cars introduced in California will have an updated C-4 system with engine-control functions. Chrysler, which has been using a computerized system not based on the microprocessor, will switch some 1980 models over to the widely used digital technology. Other functions of minicomputers in some 1980 model cars include keyless door locks, climate regulation, digital-readout dash displays, and radios. Automotive electronic applications are expected to increase dramatically in the next six years. Because some of the new electronic systems have a key role in car operation, extraordinary steps are being taken to test new hardware for reliability. The demand for microchips used with microcomputers is so large that semiconductor firms have instituted crash programs of expansion and production. Meanwhile, engineers are developing even more exotic car electronics for the mid-1980's, drawing on avionics concepts and fiber-optics technology.

SICK ENGINE? DON'T BE AFRAID OF A DIY [DO-IT-YOURSELF] VALVE JOB

General information on valve jobs is provided for the do-it-yourself car owner. Answers are provided to questions of when a valve job is necessary, what one entails, individual capability for doing the job, use of car's service manual (number 1 tool), and safety. Recommendations are given for seeking advice from the automotive machinist, for selection of replacement parts, for meeting state emission regulations, and for finding an automotive machinist shop. A short list of reference materials is provided. Step-by-step procedures and accompanying photographs are given for doing a valve job (including those aspects requiring a machinist). The photos show an overhead valve engine (1969 Ford 200 cu-in-displacement, six-cylinder). A typical valve-job checklist, and lists of parts and tools for a valve job are provided.

HONEYWELL SAVES GAS WITH FEATHERFOOT. DRIVING EFFICIENCY AWARENESS PROGRAM

Honeywell's new Featherfoot program (a 1978 update of the original 1975 program) offered incentives to the company's fleet drivers in an effort to promote more fuel-efficient driving. Drivers were grouped into six categories according to their historical mileage ranging from 13.5 mpg to 18.0 mpg for the 4500 fleet automobiles. The 2500 trucks in the Honeywell fleet were grouped in a similar fashion, by driver performance ranging from below 10 mph to over 11.5 mph. The program consisted of three, two-month competition periods from Mar 26 to Sep 23, with the winners posted after each period. Two drivers from each of the nine categories who showed the greatest improvement over the entire six months won the grand prize, an all-expenses paid, three-day trip to Scottsdale, Ariz. The top 65 in each category showing the best improvement after a two-month period received a certain number of credits (depending on placement) which were redeemed for prizes. The program was publicized with stories in Honeywell's internal journal, home mailers on prizes, and tips on "Featherfooting" (maintenance, driving technique, idling, and use of vehicle equipment). Several checks were built into the program to verify that the drivers were in fact improving their mileage. Total outlays for prizes amounted to $146,036, while total gas savings were calculated at $254,550. Average corporate gas mileage during the first quarter prior to the program was 15.4 mpg for cars and 10.1 mpg for trucks. During the two quarters the program was in progress, fuel economy improved to 16.7 mph for cars and 11.2 mpg for trucks.

THE AUTOMOTIVE POPULATION EXPLOSION

The automotive "population explosion" has already had profound effects on life in the United States and in many other nations. On the plus side, use of motor trucks has vastly widened the geographical distribution of both agricultural and manufactured products and lowered their cost. Similarly, the flexibility provided by personal transportation vehicles gives their users greater access to educational, employment, medical, shopping, and recreational opportunities. On the negative side must be listed the rising costs of vehicles and motor fuels, air pollution, loss of population and jobs in central cities of developed nations, increasing traffic congestion in foreign countries, and direct and indirect costs of traffic accidents. Recent huge increases in energy costs make it uncertain whether growth in automotive use will continue unabated in the future. Nevertheless, automotive use will continue to expand in size and impact, to at least some degree, everywhere consumers can make free choices about how to spend their incomes. The vehicle population explosion is literally shaping the world's urban development, bringing a mixture of benefits and drawbacks.

SHORT-RANGE PLANNING FOR URBAN GOODS MOVEMENT

An overview is presented of urban goods movement (UGM) problems and opportunities, and a strategy discussed for identifying short-range, low-cost opportunities for improving the UGM system which can be included in the Transportation Systems Management (TSM) plan for an urban area. Some of the typical UGM problem sources include deficiencies at shipping/receiving points (inadequate off- or on-street loading/unloading facilities, or poor access); deficiencies en route to shipping/receiving points (inadequate geometric design of roadways, lack of continuous routing in specific corridors, inadequate bridge capacity, or overhead and roadside obstacles); policies of public agencies (lack of enforcement of loading-zone restrictions, or poor land-use planning and control); and business operating policies (limitations on the use of receiving facilities, lack of centralized facilities at large complexes, or undesirable carrier response to lack of loading space). The long-range and short-range planning programs for urban transportation are subject to guidelines issued in 1975 by Urban Mass Transportation Administration and Federal Hwy. Administration. Although UGM is not specifically mentioned, some communities have included it in their transportation plans. Analysis of the UGM system consists of appraisal (by Community Quick Check, interviews with the UGM community, mail and field surveys), evaluation of alternative opportunities (quantification of UGM problems and opportunities, UGM Advisory Panel meetings), and implementation (TSM plan, Transportation Improvement Program).

HS-026 576

EVALUATING MOTOR FUEL CONSERVATION POLICIES AT THE COMMUNITY LEVEL

Criteria are presented for evaluating fuel conservation policies at the community level: size of impact area, availability of technology, presence of counterproductive factors, cost/effectiveness, conflicts with general plans, public acceptance/rejection or equitability, and amount of fuel saved. Reasons for rejection of possible fuel conservation policies are listed under each criterion. At the community level there are very few individual policies that can be implemented in the short term to achieve substantial fuel savings. Many of the policies discussed, that failed one test or another, would have also failed the final test of fuel savings. There are notable exceptions such as fuel rationing, excise taxes on "gas-guzzler" automobiles and motor fuel tax surcharges, and improvements to vehicle operating efficiencies. These either are not effective if implemented unilaterally at the local level or else require Federal mandates to stimulate technological innovation. At the community level, planners should implement long-range land use reforms and incentives that support carpool and vanpool programs, coordinating these policies with those of higher planning echelons, in order to be effective. Land-use reforms could be counterproductive unless coordinated at regional levels for large commuter sheds. Carpool and vanpool incentives must be combined with Federally-authored fiscal disincentives that discourage automobile use. Other programs with lower potential fuel saving capability are shuttle and jitney service, and bicycle and pedestrian facilities.

ACCESSIBILITY MEASURES USED TO APPRAISE TRANSPORT SYSTEM PERFORMANCE

A wide range of approaches to accessibility, as found in various environmental and urban planning disciplines, is reviewed in the attempt to find a common basis for formulating a general theory or definition of the accessibility concept. Definitions are discussed from the points of view of traffic engineering, transportation planning, environmental planning, urban economics, and comprehensive urban planning. A concept summarized from those of the above-mentioned disciplines defines accessibility as circulation that produces environmental problems; as an essential catalyst in distributing economic and social benefits; as a consumable and tradeable commodity; and as one of many activities comprising the urban way of life. Each discipline uses its own models and measures to describe and evaluate accessibility; these fall into two categories: operational measures and behavioral models. It is concluded that a comprehensive measure of accessibility is not yet available and it is recommended that planners continue to use the existing measures, selecting them according to the criteria of the nature of the problem and the period of time available for solution. Planners should also be aware that one approach does not preclude further analysis and that the environmental effects of accessibility must always be dealt with.

ALTERNATIVES ANALYSIS FOR ARTERIAL STREETS

Improving segments of arterial streets provides a means of upgrading urban transportation systems without the political controversy and delay often associated with more capital-intensive transportation improvements. Evaluating the impacts of proposed arterial street improvements, and selecting which improvement(s) should be given priority, requires a method of analysis that provides supporting documentation for informed decision making. A series of impact analysis methodologies and an eleven-step evaluation technique are described which have been used in actual practice and have proved workable. The methodologies were applied to five alternative improvements proposed for a one-mile segment of a two-way Chicago street served by two bus routes; the alternatives included continuation of the present no parking restriction from 4 PM to 6 PM, northbound; no parking in either direction, same hours; exclusive bus lane northbound (4PM-6PM); parking permitted in both directions; and traffic engineering improvements (additional left turn lanes and progressive signal timing). Impact classification schemes are tabulated and classified under eight functional categories: transportation, economic, environmental, community facilities and services, relocation, aesthetics, social, and financial. The unit of measurement is indicated for each category, as well as the methodology for estimating impact. Each of the 11 steps in the evaluation technique is discussed and a sample achievement matrix is supplied for the Chicago street. The alternative of traffic engineering improvements was judged better than any other alternative.

MOTOR VEHICLE STATISTICS OF JAPAN 1979

Japanese motor vehicle statistics are tabulated and graphed through the year 1978. Vehicle-in-use data are provided for cars, trucks, buses, and special-purpose vehicles, 1956-1978; diesel vehicles, 1961-1978; and vehicles by year of first registration, 1978. New registration data cover cars, trucks, and buses, 1956-1978; 1976, 1977, 1978 by months; new import car registrations by make, 1974-1978; and 1969-1978 registrations by make. Production statistics are given for cars, trucks, and buses, 1956-1978; 1976, 1977, 1978 by months, 1956-1978 by make; cars by cylinder capacity, 1966-1978; buses by passenger capacity, 1966-1978; and trucks by loading capacity, 1966-1978. Import data cover cars, trucks, buses, and other, 1972-1978; and 1978 imports by countries of origin. Export data cover cars, trucks, and buses, 1956-1978; 1961-1978 by make; and 1978 exports by destinations. Statistical information on motorcycles and motor scooters includes that for vehicles-in-use, 1956-1978; production, 1956-1978; production by months, 1976, 1977, 1978; production by make, 1956-1978; factory sales to domestic market, 1961-1978; exports, 1956-1978; and 1978 exports by destinations. A list of member manufactures, with addresses, is appended.

GUIDE TO THE MOTOR INDUSTRY OF JAPAN 1979

The position of the automobile industry among Japan's other manufacturing industries, and the growth of the country's auto industry are briefly described, accompanied by glossy, color photographs of Japanese highway systems and new vehicle models. Offices, plants, historical and present record, and main products are listed for each of the motor vehicle manufacturers. A general catalog is provided of representative models (passenger cars, commercial vehicles, motorcycles and mopeds) offered by the automakers as of 31 Mar 1979. Black-and-white photos of the models are accompanied by primary vehicle specifications. Photos and descriptions are also provided of some of the representative automotive parts, testing equipment, and tools. Detailed specifications are tabulated for all the makes/models of passenger cars, trucks, buses, tractors and truck cranes, and two-wheelers. Motor vehicle statistics (production, exports, registrations) are tabulated. A directory is presented of automotive organizations and manufacturers.

CHARACTERISTICS OF AUTOMOTIVE FLEETS IN THE UNITED STATES 1966-1977

All known available sources that contain statistics on fleet vehicles in the U.S. are described. Fleet operations in the U.S. are characterized according to stock composition and operational characteristics. Properties of fleet cars are compared with those of the total car population, which is dominated by cars for personal use. Elements considered include purchase decisions, differences in stock composition (especially size breakdown), and differences in operating characteristics. A comparison is made among fleets used by different sectors, such as business, utility, and police. The significance of fleets to transportation energy conservation is addressed. Principal findings include the following information: there is no universal definition of fleet; cars sold for fleet use represent 13% of total new car retail sales; cars in fleet service of ten or more cars represent 6.5% of the total U.S. car stock; business fleets dominate the fleet stock (46%); individually leased and daily rental fleet categories exhibit the fastest growth (12% and 8% per year, respectively); standard size fleet cars are being replaced by new smaller intermediates with downsized engines; fleet cars are driven more mi/yr than cars in general; efficiency improvements on new cars are implemented in fleets more quickly and filter to the general public faster through the used car market; and fleets offer some special opportunities for new or limited-performance vehicles.

HUMAN FACTORS REQUIREMENTS FOR REAL-TIME MOTORIST INFORMATION DISPLAYS. VOL. 1, DESIGN GUIDE. FINAL REPORT

Practical guidelines are provided for the development, design, and operation of driver displays, both visual and auditory, for freeway traffic management. Emphasis is placed on the recommended content of messages to be displayed in various traffic situations; the manner in which messages are displayed (format, coding, style, length, load, redundancy, and number of repetitions); and location of messages with respect to the situations they are explaining. In addition to data on developing effective message content, information is provided on types and characteristics of changeable message signs, and on sign visibility and legibility criteria. The guidelines for incident management/route diversion situations are based on both research and operational experience and are basically restricted to information displays for freeway corridors.

AUTOMOTIVE DEVELOPMENT. HEARING ON GOVERNMENT/INDUSTRY ROLES IN FUTURE AUTOMOTIVE DEVELOPMENT, MARCH 23, 1979

Testimony from a congressional hearing on future automotive technology is presented, with additional supporting articles, letters, and statements. This hearing was convened to address the current status and future potential of automotive development in particular view of the energy crisis. Witnesses included the Secretaries of Transportation and Energy, congressmen, the Director of the Office of Technology Assessment, and representatives from Ford Motor Co., General Motors Corp., American Motors Corp., and Chrysler Corp. Additional material was submitted by government officials, the auto industry, research organizations, academia, and public interest groups.

DIABETIC FIGHTS FOR RIGHT TO GET A CLASS A LICENSE

Marla Ellery of Burlington, Ontario is challenging a Canadian regulation (Regulation 906/76 of the Highway Traffic Act) which bans diabetics who use insulin from driving trucks over 18,000 lb. This restriction was added on the advice of diabetes specialists who stated that diabetics are subject to seizures which could cause them to lose control of a vehicle (position of the Canadian Medical Assoc.). Mrs. Ellery says she has never had a problem with her illness in the 20 years she has been a diabetic. After completing the Canadian Inst. of Tractor Trailer Training course in Sutton, Ont. in 1973 with a 98% mark, top in the class, Mrs. Ellery drove trucks in the range of 23,000lb to 43,000 lb. She now has a "G" license, which allows her to drive a tractor-trailer if an "A" licensed driver is in the cab. The U.S. Federal Motor Carrier Safety Regulation similarly bans diabetics who use insulin from operating a motor carrier. Mrs. Ellery has been undergoing tests at the MacMaster Univ. Medical Clinic; an opinion will be submitted to her family physician and the Ministry of Transportation and Communications. The examining physician at the Clinic says that the decision of whether diabetics should be allowed to drive big trucks depends on the individual case. In the meantime, Mrs. Ellery is soliciting letters from other diabetics who are truckers and will take the correspondence to the Ontario government and plead her case.

IN AUTO SHOWROOMS: THE CONSUMER ONCE AGAIN BEGINS TO THINK SMALL

Sales of small cars, both domestic and imported, soared in the U.S. in the first half of 1979 as gas station lines, concern over gasoline availability, and rapidly rising gas prices increased consumer demand for more fuel-efficient cars. Sales of domestic subcompacts and compacts followed the same pattern as imported cars, with slow sales early in the year and a sharp increase beginning in Mar. Including foreign autos, small cars made up over 60% of May sales. A Commerce Dept. projection puts total small car sales in 1979 at 10.6 million (2.3 million imports and 8.3 million domestics). Dealers' inventories of domestic new cars are estimated to have reached a record 2 million units at the end of May. The inventory situation reversed from Jan, when small cars were overstocked and large cars were in tight supply. In general U.S. automakers are unable to increase production to meet the small-car demand. A larger increase in the production of small cars cannot be achieved before the 1981 model year. Even if the shift is short-lived, it is unlikely that consumers will ever purchase as many large cars as in 1978. Car production in model year 1979 will probably total 8.8 million units (about 3.9 million subcompacts and compacts, some 4.9 million larger models). For the next model year as a whole, the Commerce Dept. projects that about 8.2 million cars will be produced (of these probably less than 4 million will be larger cars). The decline in auto production will have a large impact on employment in the industry and its suppliers of materials (rubber, zinc, aluminum).

HOW TO CHECK, SELECT AND REPLACE SHOCK ABSORBERS

The components of a shock absorber are illustrated, and absorber function and operation described. Signs are outlined which indicate that shocks need replacement. Two important tips are mentioned: if one shock needs to be replaced, so does the other shock on the same axle; replacing shock absorbers will not solve riding and driving problems caused by other conditions. Information is given on the three general types of shock absorbers: replacement (OEM-COMPARABLE (original equipment), heavy-duty, extra-heavy-duty, adjustable, or MacPherson), load-carrying (shocks combined with coil springs), and special-purpose (include those for racing cars, medium and heavy trucks, and buses). It is advised not to buy shocks unless they are accompanied by instructions. A list is provided of some "do's" and "don'ts" to guide an individual car owner ("Saturday mechanic") in replacing shocks. A separate section describes the evolution of the modern shock absorber.

A THEORETICAL MODEL TO ESTIMATE SOME ERGONOMIC PARAMETERS FROM AGE, HEIGHT AND WEIGHT

A model to predict some anthropometric, biomchanical, and work physiology parameters from age, height, and weight is described, including its capabilities and restrictions. Predicted values of 83 ergonomic parameters for a sample of 250 healthy males show close agreement with the observed values reported in the available literature. The model requires updating and refinement when more exact formulae become available. Development of a similar model for the female population is needed. Inclusion of psychological parameters such as the human reaction time, channel capacity, and information processing capability, is highly desirable. Effects of noise, heat, vibration, and illumination on human performance and comfort need to be quantified as to age, weight, and height. Proper use of the model will provide useful data for design purposes. Industrial applications of this model include pre-employment screening, job placement, in-plant physical fitness programs, job classification, work-rest scheduling, and workplace design.

SPEED/FLOW RELATIONSHIPS IN ROAD TUNNELS

Traffic speed and flow data were recorded at nine road tunnels in England and Scotland at various times between Oct 1972 and Aug 1976 in order to determine speed/flow relationships. At two sites, speeds were also recorded on sections outside the tunnels. The speed/flow values for the observed tunnels fall generally within the area of data obtained for suburban main roads and are somewhat lower than those found for rural main roads. The typically wide scatter of speed/flow observations at individual sites and the considerable difference in patterns between sites do not permit the establishment of separate speed/flow relationships for the tunnels. From the limited evidence at the two sites where speeds were measured on the open road adjacent to the tunnel, it is concluded that short, straight, well-illuminated tunnels do not markedly affect traffic speeds.

PREDICTION OF THE FUEL CONSUMPTION OF HEAVY GOODS VEHICLES BY COMPUTER SIMULATION

A computer simulation model of the fuel consumption of heavy goods vehicles (commercial trucks) is described, and results of validation tests provided. The model was designed to represent different vehicle shapes, power plants, and transmission systems, as well as the interaction of the vehicle and driver over road routes. The driver was characterized by the use of the accelerator (percentage engine load) and gear selection. Different operating conditions were simulated and results compared with those produced by an instrumented tractor/flatbed trailer combination operating at different gross vehicle weights (GVW). A comparison was made over short distances and defined conditions on the Transport and Road Res. Lab. test track. Large percentage differences in fuel consumption were found when small amounts of fuel were used over short distances, but good overall agreement was achieved. The largest discrepancy occurred in the unladen condition on the test track, a condition which coincided with the least accurate input data. When longer road routes, including sections of urban and rural roads and highways, were simulated, the model accurately predicted the fuel consumption for all GVW'S tested.

SPEED CONTROL HUMPS IN KENSINGTON AND GLASGOW

Speed control bumps designed at the Transport and Road Res. Lab. have had a one-year trial on two public roads; Abbotsbury Rd., Kensington (England) and Barlanark Rd., Glasgow (Scotland). Details are given of the method of construction of the bumps and the effects of installation on public opinion, traffic, and accidents. The speed bumps on these roads appeared to be effective in reducing vehicle speed and traffic flow. The marginal reduction in the number of traffic casualties on each of the roads was not statistically significant. Although no increase in accidents was noted on possible alternative routes to Abbotsbury Rd., there was an increase on the roads surrounding Barlanark Rd., possibly related to diverted traffic. The bumps were acceptable to the majority of both residents and drivers who continued to use the roads.

CAR POOLING: TRAVEL TO WORK AT AN ISOLATED SITE

As part of a study of the use of cars in peak periods, staff at an isolated, rural workplace in Berkshire, England were surveyed to determine how they traveled to work. The survey concentrated on the choice between driving alone and carpooling. Information was obtained via a questionnaire from the approximately 700 employees (greater than 90% response) and a follow-up survey of carpoolers (90 out of 99 contacted). As expected, carpoolers were more likely than solo drivers to live in urban areas. Carpoolers' trip lengths had a smaller range (5 km to 25 km) than that of solo drivers; for short journeys, it is not worth forming a carpool, and for long journeys, it is difficult to find people with whom to form a carpool. Only about half the carpoolers picked up their fellow passengers at home; in the other pools, the passengers walked or drove to a convenient meeting place. The survey results were modeled using a Logit model in an attempt to quantify factors affecting the choice of single drivers and carpoolers. Although the results are subject to large errors, it is indicated that diverting 1 km to meet a carpool partner is perceived to be about as inconvenient as traveling an extra 5 km. The study indicated that increasing the marginal cost of driving by 25%, or imposing a parking charge of 10 p/day more for solo drivers than the average paid by carpoolers, is likely to cause about 5% of the solo drivers to carpool.

ACCIDENTS INVOLVING HEAVY GOODS VEHICLES [COMMERCIAL TRUCKS] IN GREAT BRITAIN: FREQUENCIES AND DESIGN ASPECTS

An overview is presented of the contribution of heavy goods vehicles, (HGV'S, commercial trucks) to the road accident situation, based on 1974 data for Great Britain but probably reflective of situations in other European countries. Accident-avoidance features that can be incorporated into HGV'S are discussed, as well as design features to reduce injuries to other road users. The risk of a medium or heavy goods vehicle being involved in a serious accident in the U.K. has been reduced almost by half in ten years, down to about 27 trucks/100 million km traveled in 1975 (slightly lower than for a car). HGV'S are disproportionately accountable for casualties to other road user types. Improvements in tire traction on wet roads, braking system performance, loading and load-securing techniques, and design features affecting rollover and compatibility with other vehicles could aid in reducing HGV accidents. Auxiliary brakes and retarders may cause loss of control if not properly matched to the service brake system. Bumpers at heights matching those of cars and energy-absorbing structures would reduce casualties to restrained occupants of smaller vehicles in front and rear impacts. The front structure of HGV'S is more important than the rear in terms of accident frequency. Improved cab designs could reduce the incidence of crushing and trapping of truck occupants. Higher power-to-weight ratios without precautions to control drive axle spin up will increase the risk of loss-of-control accidents. Proposed regulations need to be validated by full-scale experiments.

THE DYNAMICS OF VEHICLES ON ROADS AND ON TRACKS. PROCEEDINGS OF 5TH VSD [VEHICLE SYSTEM DYNAMICS]- 2ND IUTAM [INTERNATIONAL UNION OF THEORETICAL AND APPLIED MECHANICS] SYMPOSIUM HELD AT THE TECHNICAL UNIVERSITY VIENNA, AUSTRIA, SPETEMBER 19-23, 1977

Thirty-eight papers, presented orally at an international symposium on vehicle-road and vehicle-track dynamics, particularly addressed problems involving the contact or guiding forces which act between vehicle and road surface or vehicle and guiding track. Specific attention was given to new methods and techniques for studying system dynamics. Lateral dynamics, stability, control analysis, and riding comfort on rigid or elastic supports were covered during eight sessions; five sessions were devoted to road vehicle mechanics and the other three to track-guided systems. The sessions were grouped according to vehicle type, ranging from motorcycles to truck-trailer systems and magnetically levitated trains.

FRONT WHEEL VIBRATIONS

The fundamental aspects of wheel suspension/steering system dynamics with and without road contact are examined. Possible means are analyzed to reduce the system sensitivity to external disturbances such as wheel unbalance, and to compensate for vibrations caused by tire nonuniformity. The in-plane behavior of the tire is considered separately. An outline is provided of the development of a computer program, FROVIB (Front Wheel Vibration), for the frequency response analysis of complicated suspension-steering systems. The program can analyze systems with either an unloaded freely rotating wheel or a rolling tire that has dynamic rolling contact properties. The program is valid for such suspension configurations as trailing arm systems, wishbone suspension systems, McPherson systems, or modified McPherson with flexible upper mount.

THE INFLUENCE OF THE STRUCTURE OF AUTOMOBILE MODELS AND TYRE [TIRE] CHARACTERISTICS ON THE THEORETICAL RESULTS OF STEADY-STATE AND TRANSIENT VEHICLE PERFORMANCE

The effect is analyzed of the mechanical description of the car and the mathematical approximation of the tire behavior on the theoretical simulation of vehicle performance. Two four-wheel car models are used to derive the governing equations; the first model explicitly considers the suspension car body interaction while the second derives the four normal wheel forces by an additional equation. Two different approximations of tire characteristics are utilized, and a bias and a radial tire are compared. The path taken by the vehicle consists of a straight track, a transient spiral, and a bend of constant curvature, with changes in superelevation. With respect to wheel contact force ratios, it was found that the tire approximations had a greater and less satisfactory effect than the vehicle modeling. In terms of vehicle handling, the advantages of the first model are counterbalanced by a less detailed description of the tire behavior. The differences between bias and radial tires in terms of tire contact and vehicle handling are so important that there can be no comparison between vehicle model/tire approximation combinations using different tire types. For normal acceleration less than 0.4 g, every model/approximation combination with the same tire types can be utilized.

DYNAMICAL ANALYSIS OF SUSPENSION SYSTEMS

Suspension systems with spatial kinematics are modeled by multibody systems consisting of rigid bodies, springs, shock absorbers, and joints. The nonlinear and linearized equations of motion are derived in symbolic form using a computer. Symbolical equations of motion assure minimal computation time in the dynamical analysis of suspensions. A dynamical analysis is presented of the vehicle's ride comfort, safety, and joint forces. As an example of the method's application, the transversal link suspension of a completely symmetrical vehicle is analyzed. The equations of motion are shown in the nonlinear version, and a design parameter is optimized in the linearized version. The method may be more advantageous for more complex asymmetrical suspension models.

A COMPARISON BETWEEN FOUR COMPUTING MODELS OF DIFFERENT COMPLEXITY DESCRIBING THE STEERING BEHAVIOUR OF TWO-AXLED AUTOMOBILES

Four simulation models of different complexity for describing the steering behavior of two-axled automobiles are compared to demonstrate the degree of complexity required to solve a specific problem. Model 1 (the most complicated) evaluates tires, suspensions, steering, spring, damping, and the most important interactions very accurately. Model 2 is a four-wheel model with a specific roll axis. Several nonlinearities are simulated as functions of spring deflection. Model 3 is a simple four-wheel model with nonlinearities only for the simulation of the tire characteristics. Model 4 is a simple two-wheel model. The computing time needed to solve the same problem increases from model 4 to model 1 by the following proportions: 1, 2, 5, and 50. The two-wheel model gives qualitative results only, but the improved four-wheel model (model 2) with four degrees of freedom and good approximations of the nonlinear characteristics of tires, springs, steering, steering compliances, and damping provides an accurate simulation of actual vehicle behavior.

TRANSIENT CONTROL RESPONSE OF AUTOMOBILES

A comparatively simple, three degree-of-freedom model is described for investigating the transient control responses of four-wheel vehicles and the influence of design factors on such responses. The procedure and analysis method for measurements of vehicle frequency responses from a pseudo-random steer input test is presented with results to illustrate the quality of the test, and its ability to detect vehicle changes. The relationship between steady-state response and transient response is discussed. Examples show the very important contribution to the overall transient response that can be made by the geometrical and compliance losses in the steering systems. Although yaw-rate response time has previously been considered the most important transient response parameter, the author considers that lateral acceleration response, response gains, and steering torque characteristics play an important role in the subjective evaluation of steer response.

THEORETICAL INVESTIGATION ON NON-STEADY-STATE DRIVING CONDITIONS OF A MOTOR VEHICLE

The vibrations occurring within the transmission system of a motor vehicle under transient driving conditions are theoretically investigated, with emphasis on the initial acceleration of a passenger car. An eight degree-of-freedom vehicle model is presented which contains 39 independent parameters. Using 12 of these parameters, a tire theory is introduced which makes it possible to calculate transient longitudinal shear stress distributions along the tire contact patch of the driving wheels for each point in the acceleration process. Numerical calculations are presented for a passenger car with a specific wheel suspension. Peak values of transmitted torques within the driving system are calculated, and the transient tire behavior is expressed primarily in terms of the adhesion coefficient and tire slip, the steady-state relation between these parameters having been found invalid for describing tire behavior under acceleration.

COMPUTING AND MEASUREMENTS OF THE HANDLING QUALITITES OF THE BELTED TYRE [TIRE]

The deformation behavior of the inflated, prestressed system of a tire's belt and carcass is computed. Good agreement is found between calculations and measured results, which show that the contact pressure distribution and lateral deformation under side load can be computed by tire design parameters. An optimal design of the tire cross section is therefore possible. The influence of the belt on the elastic deformation of the tire material is shown. The overall shear stiffness of construction is strongly dependent on load and should be computed from measurements; the bending stiffness of the belt is not dependent on load. Cornering forces are computed by a three-band model of contact patch and show good agreement with measured results. The influence of the contact patch on cornering forces gives rise to a second order differential equation for determing the lateral deformation of the belted tire during quick steering maneuvers.

A GENERAL PURPOSE PROGRAM FOR THE SIMULATION OF VEHICLE-GUIDEWAY INTERACTION DYNAMICS

A general-purpose digital computer program is described for the dynamic simulation of tracked high-speed ground transportation system vehicles and their interaction with guideways. The program, which has application to a broad class of transportation systems, eliminates the need for numerous specialized programs. The models which can be treated are as follows: multibody rigid or elastic vehicles, any degrees of freedom, kinematic constraints; a variety of linear and nonlinear suspension laws including active control systems; elastic guideways (or bridges) including irregularities; and straight or curving motions (curves, grades), and travel at constant or variable speed. Special features of the resulting simulation program are automatic generation of the linearized system equations, generation of subroutines to reduce the numerical effort, and modular construction of the whole program. The time response of the overall time-varying and possibly nonlinear-state equations is obtained via numerical integration. The program is supplemented by evaluation and interpretation routines which allow computation of vehicle stability, controllability, and observability as well as the transfer function matrix. The time responses can be Fourier-transformed and vehicle ride quality calculated. As a typical application, the simulation of an electrodynamic repulsion system design is presented, for both the magnetically suspended as well as the emergency mode.

PERFORMANCE OF STEERING CONTROLLERS FOR AUTOMATED GUIDEWAY TRANSIT VEHICLES

The conflicting requirements of tracking accuracy and passenger comfort are discussed as they affect the performance of automatically steered, rubber-tired vehicles on both straight and curved guideways. The optimal performance for operation on straight guideway containing random lateral reference errors is presented. This performance, the best achievable with any controller of the class considered, provides a standard against which simpler, suboptimal controllers can be evaluated. A simple proportional controller using a single displacement sensor is shown to produce near-optimum performance for the typical vehicle studied when operated at the design speed. Performance of the proportional controller on curved guideway is simulated to evaluate tracking errors and ride comfort. It is shown that by appropriate location of the position sensor, steady-state errors in curving can be made small for the practical range of curve radii. Curve entry transients are simulated for a curve having no transition spiral and a steady-state lateral acceleration of 0.223 g at 13.4 m/sec. Acceleration and tracking error overshoots are both less than 13.3% for well-chosen gains. These results suggest that a simple proportional controller can yield good performance on both straight and curved guideways for a vehicle having well-designed open-loop dynamics.

FEASIBILITY OF A FOLLOWER TYPE TRAFFIC STRING CONTROL

A numerical and analytical study of the feasibility of an onboard vehicle control of traffic strings (distance between following vehicles) is presented. The control logic for the individual vehicular control is based entirely on the absolute velocity of the vehicle and its relative displacement and velocity to the preceding vehicle. All are easily measured quantities, and the resulting control gives constant time-headway spacing. The required hardware elements include a velocity transducer, a radar, a microcomputer, and an activator system. It is expected that most of the position keeping control will be accomplished by throttling, braking being reserved for emergency or near emergency situations. The throttle control is combined with cruise control which the driver can engage at will. Power or vacuum assisted brakes make braking control easier. The entire control system can be overridden when the driver wishes, at which time it is switched off automatically until reset. Stability properties are considered from a systems viewpoint involving the entire traffic string rather than one or two vehicles. The dynamic system does not include automatic steering and thus has easily adaptable dual-mode characteristics.

AUTOMATIC TRACK CONTROL OF VEHICLES. THEORY AND EXPERIMENT

The theoretical and experimental work involved in the development of a bus which operates under lateral track control is described. In this vehicle a controller performs the steering normally done by the driver. The following research areas are discussed: derivation of a vehicle model, measuring the vehicle frequency responses, analyzing the developmental steps necessary to obtain optimal vehicle behavior, describing and evaluating the design methods used to find optimal controllers, and experimental testing of the vehicle driving behavior. A prototype vehicle was constructed and driving tests were performed on a special test track.

ON THE DIRECTIONAL REPSONSE CHARACTERISTICS OF HEAVY VEHICLES

The cornering performance of heavy trucks incorporating multiple, nonsteering rear axles and dual tires is examined in the linear regime to identify how this performance differs from that of the simple two-axle, four-wheel vehicle. Multiple, nonsteering rear axles and dual tire arrangements are seen to increase the steer angles required to negotiate a turn because these elements produce a moment resistant to turning. Vehicles which have these elements may be characterized by an "effective wheelbase" which is greater than the geometric wheelbase. Experimental data are shown which verify steer angle predictions made using this characterization. "Effective wheelbase" depends on tire stiffnesses, as well as vehicle geometry, and thus is dependent on loading conditions. An optimum wheelbase for highest maneuverability is shown to exist. Because cornering is dependent on "effective wheelbase," errors can occur in measurement of truck understeer/oversteer gradients if this dependence is not properly taken into account. To avoid such errors, the constant radius test method is recommended. The effect of speed on heavy-truck cornering is characterized by an understeer expression similar to that for simple vehicles, and is dependent on the geometric wheelbase. Because of the load dependence of the low speed steer angle term, it is observed that trucks may respond differently to fore/aft center of gravity shifts. Specifically, conditions are cited for which path curvature gain may increase with forward shifts of the center of gravity, a result which is contrary to behavior typical of passenger cars. The transient response of heavy trucks is likewise considered in order to determine the effect of multiple, nonsteering rear axles and dual tires on directional damping, natural frequency, and response time. Losses in limit cornering capability deriving from these design arrangements are also discussed. The reduction in the turn resisting moment occurring at limit maneuver performance conditions is important in contributing to vehicle "spin out" tendencies.

A MODEL OF THE SEMI-TRAILER VEHICLE INCLUDING ROLL MODES

An articulated vehicle (tractor-semitrailer) model is described which has six degrees of freedom (tractor forward speed, lateral velocity, yaw velocity, and roll angle, and trailer articulation and roll). The origins of the axis system are located at the theoretical hinge position of the fifth wheel coupling. The kinematic effects of the coupling are described; the coupling is also assumed to act as a torsional restraint with the torsion axis aligned with the x axis of the tractor. The model is shown to compare with previous articulated vehicle models developed by the author, and a program of study is described which examines the performance of the articulated vehicle while negotiating a traffic circle.

PITCHING AND BOUNCING DYNAMICS EXCITED DURING ANTILOCK BRAKING OF A HEAVY TRUCK

A simulation model previously refined by C. C. MacAdam is used to investigate sustained pitching and bouncing oscillations during antilock braking of a heavy truck. Calculated time histories of deceleration, pitch, bounce, and axle loads are presented to describe the form of the observed oscillations. Energy concepts are used to analyze a typical cycle of the sustained oscillations, and conditions under which the oscillation amplitudes increase or decrease are discussed. Computer analyses showed that the baseline vehicle will exhibit severe pitching and bouncing motions and degradation of stopping performance under the following combination of conditions: a high center of gravity load; a good, uncontaminated road surface for making the stop; typical levels of brake imbalance and hysteresis; and an antilock system which tends to reduce the air pressure in the brake chambers to atmospheric pressure after wheel lock becomes imminent. Results of a parametric study indicate that changes in brake and suspension properties typical of in-service variations have a significant influence on the pitching and bouncing of the baseline vehicle; that the influence of pitching and bouncing can couple with antilock system operation to degrade stopping distance; and that a pressure modulation scheme which controls the level of pressure reduction during antilock cycling would be effective in attenuating pitching and bouncing while reducing stopping distance for the baseline vehicle.

ROAD SURFACE DESCRIPTION IN RELATION TO VEHICLE RESPONSE

Single-profile description of a road surface as a random process has proved an effective basis for vehicle response analysis. More realistic response analysis requires the description of profile-pairs (descriptions of near- and off-side tracks made by vehicles). Adoption of the hypothesis of isotropy, together with a single road-profile description, permits an entire surface to be described simply. A particular profile description can then be made the basis of an isotropic model from which the required track cross-spectra can be derived for any desired track width. Coherency functions obtained from this model have been compared with measurement-based coherencies for a variety of roads. It is concluded that the isotropic model is of value where approximation rather than precision is required.

THE EFFECT OF ROAD ROUGHNESS ON VEHICLE BEHAVIOUR

An experimental and analytical study demonstrates the effect of road roughness on the driver-vehicle system in terms of driver vertical acceleration (ride quality), lateral tire forces (related to vehicle handling), and normal tire forces (acting between the road surface and the tires). By establishing acceptable levels for these quantities, it is possible to set limits for road roughness. It is theoretically possible to assume any desirable vehicle response power spectrum and, using the vehicle transfer function, determine the road roughness power spectrum.

DYNAMIC RESPONSE OF TRACTOR-SEMITRAILER VEHICLE TO RANDOM INPUT

A dynamic analysis of the vehicle-road system is provided, using the theory of stochastic processes, including the vibrations transmitted from the roadbed to the tractor-semitrailer and the dynamic forces at the tire-road interface. The tractor-semitrailer vehicle is treated as a discrete, linear, time-invariant, dynamic system subjected to a stationary random input from the road surface. The vehicle model, including primary and secondary suspension systems, and subject to both heave and pitch motions, has six degrees of freedom. A representation of random roughness of the road is given, frequency domain analysis is applied, and a parametric study is presented. Results of the computer analyses are presented in two forms: the amplitude spectra and the root mean square amplitudes which are used to predict vehicle ride quality and to evaluate design concepts. The effects of suspension spring and damping characteristics, tire spring characteristics, and vehicle speed on the vehicle dynamic response and road-vehicle interaction are demonstrated.

THE STEADY-STATE-BEHAVIOUR OF A TRUCK-TRAILER-SYSTEM CARRYING RIGID OR LIQUID LOAD

The tractor-dolly-trailer system and its load are modeled, and equations of motion are derived for analyzing the steady-state behavior of the tractor-semitrailer system under different load, steering input, and speed conditions. Calculations are presented for a typical vehicle system under different loading conditions. The strong influence of the specific type of load (solid or liquid), degree of loading (maximum load or unloaded), and load distribution upon vehicle handling characteristics is demonstrated, as well as the strong dependence of the vehicle behavior on the frequency of harmonic steering corrections and on steady-state speed.

AUTOMOBILE STABILITY; A STUDY OF THE DOMAINS OF ATTRACTION

Stability criteria are examined in a vehicle assumed to have two degrees of freedom (lateral and yaw motions) with constant forward speed and steer angle. It is shown that the boundary of the stability domain (domain of attraction) can be synthesized by generating two sign definite potential functions satisfying Zubov's partial differential equation. A computer algorithm is developed to accomplish a numerical solution. It is inferred that all limits of unit impulse force and couple-vectors belong to the bounding surface of the domain of attraction. The limit of wind gust intensity and its effect on the stability of vehicle motion are discussed as an example.

THE USE OF SYSTEM IDENTIFICATION METHODS FOR THE DETERMINATION OF VEHICLE PARAMETERS FROM MEASURED TIME HISTORIES

Methods for the objective description and evaluation of vehicle control dynamics are discussed, especially vehicle response to steering input. Objective analysis entails numerical expression of steering control behavior and desirable ranges for vehicle dynamic parameters. The theoretical background of suitable methods for determination of vehicle parameters from measured time functions is presented. Some results of practical applications using time histories measured in open-loop tests are given; these applications concern single vehicles, as well as car-trailer combinations. Proprosals for simplification and unification of the described methods are presented. It is noted that yaw transfer function (gain factor, numerator time constant, damping ratio, and natural frequency) parameters on tested vehicles covered a wide range of values and that relationships could be determined between these parameters and subjective judgments of driveability.

DRIVER-VEHICLE INTERACTION WITH RESPECT TO STEERING CONTROLLABILITY

Theoretical and experimental studies have been made of the steering control quality of two different vehicles during lane change maneuvers. In the first vehicle, the weight was increased, and the weight distribution changed between the front and rear axles. The air pressure in the rear tires was reduced at various stages in the second vehicle. The experimental tests comprised measuring of vehicle characteristics, subjective rating of steering control quality, and measuring the performance of the driver-vehicle system in terms of following a designated course. Results show that there is a strong relationship between yaw velocity response time, steering wheel angle gradient, steering torque gradient, and subjective rating. It was shown that yaw velocity response time is the dominant factor, greatly influencing steering control quality in transient steering maneuvers, with relatively high lateral acceleration.

THE INFLUENCE OF VEHICLE CONTROL DYNAMICS ON DRIVER-VEHICLE PERFORMANCE

The influence of steering system and vehicle response characteristics on driver performance was investigated under both simulated and actual driving conditions. Simulator characteristics were matched to those of the full-scale vehicle with respect to steering torque gradient, control sensitivity, and lateral acceleration response time; identical disturbance signals were applied in each facility. The influence of torque gradient was accentuated in the simulator and at low levels of control sensitivity, with high levels of torque gradient producing smaller steering wheel and vehicle motion deviations. The effect of control sensitivity on steering wheel deviations was accentuated under actual driving conditions and for slower response times. A greater improvement in lateral position deviations with increased control sensitivity was also noted for the slow response time configurations. Overall the two facilities showed a high degree of correspondence at the different matched settings. The results also indicate that vehicle parameters must be investigated in combination in order to determine their effect on driver-vehicle performance.

THE STRAIGHT-RUNNING STABILITY OF SINGLE TRACK VEHICLES

A new theoretical treatment of the straight line stability of motorcycles is provided. It was developed from previous treatments, and involves elaboration of the tire models employed. In the absence of adequate experimental data for motorcycle tires, the taut string analogy is utilized as a basis for estimating tire dynamic properties following lateral or yaw disturbances, and recent results allow better modeling of the responses to camber. Empirical fitting to the lateral and yaw responses leads to the establishment of a linear, constant coefficent set of equations of motion, from which stability characteristics are found by standard procedures. Results are included to show the importance of the various facets of the tire model. The results show that the more elaborate tire modeling effects significant changes in predicted stability characteristics. In particular, the predicted damping of the wobble mode is reduced, which may well bring better agreement between theory and experiment. The effects are not dramatic, indicating that conclusions of previous studies using simpler tire representations should be, for the most part, valid. Modeling and experimental study requirements are proposed.

DYNAMICAL ASPECTS OF PASSENGER CARRYING VEHICLES USING CONTROLLED D.C. ELECTROMAGNETS

The use of controlled DC electromagnetic suspension systems for passenger-carrying vehicles poses a number of special problems, such as interaction through vehicle dynamics and different control loops, noncyclicity of the system, and the choice of weighting matrices for high-order systems. In order to develop synthesis procedures for active feedback systems, it is necessary to consider static and dynamic interactions between various degrees of freedom such as roll, pitch, yaw, lift, and lateral displacement. In addition to stability requirements, other characteristics associated with vehicle dynamics must be considered, such as ride comfort, suspension stiffness, operating speed and air gap, and effects of vehicle-guideway interaction. Different methods of designing feed-back control systems have been studied. A principal problem has been shown to be cross-coupling and interaction between controllers; methods of achieving dynamic decoupling have been indicated. It has been shown that the weight of the vehicle can be distributed to obtain a large zone free from natural frequencies; this will have practical significance in the choice of natural frequencies of the various suspension stabilization control systems. A flexible chassis has been shown to increase suspension system stability as well as ability to handle warped tracks. Active feedback of relative position, absolute velocity, and absolute acceleration to meet ride comfort criteria and stability, as well as flexible chassis, offers promise for both high- and low-speed applications.

VARIATION OF CONTACT WHEEL-TAIL [RAIL] FORCES AFTER OVERREACHING CREEP-SLIP ADHESION BOUNDARY

A dynamic analysis is provided of wheel-rail forces in an individual axle-driving system of a diesel locomotive after the creep-slip adhesion boundary has been exceeded. A seven degrees-of-freedom model represents a rigid car body, a bogie frame, primary and secondary suspensions, a resilient wheel, and an axle-hung traction motor. For this model, the linearized characteristic of the traction motor for the specific speed range and experimentally-measured creep-slip characteristics are assumed. The resulting equations of motion were solved for a particular driving system via computer. It was found that the main influences on the magnitude of the wheel-rail forces after the creep-slip transition were the value of the damping coefficient, the ratio of moments of inertia, the slope of the electric motor characteristics and the slope of the creep-slip characteristics. There exists a limiting value of the damping coefficient of an axle-driving system for which the magnitude of the wheel-rail forces are negligible and no self-excited vibrations in the driving system can occur. Theoretical predictions were found in good agreement with experimental results.

THE BEHAVIOUR OF TRACTIVE UNITS AT SKIDDING WITH DIFFERENT KINDS OF PROPULSION AS A DYNAMICAL AND A STATISTICAL PROBLEM

The tendency towards slipping and the various phenomena occurring during slipping of locomotives are considered. Calculations and experiments show that the slipping process depends on the value as well as the speed characteristic of the frictional coefficient. The friction-slip relationship as expressed by Mensutin (1960) is used in the present analysis. Types of slipping processes (creep-slip, rapid slip, increasing "chattering" leading to "runaway" slip, and "chattering" slip) are discussed. Statistical characteristics of the random value of friction are mentioned. The slipping probability is analyzed of locomotives of conventional and innovative design (undulatory current, three-phase, and electrohydraulic drives). The influence on slipping probability of locomotive body and bogie spring suspension is considered, as well as that of velocity. Structural formulae for the slipping behavior of conventional and developmental locomotive drives are provided and discussed. The advantages of three-phase and electrohydraulic drives, and research results on their slipping behavior are also discussed.

RESPONSE OF DIESEL COMBUSTION SYSTEMS TO INCREASE OF FUEL INJECTION RATE

The improvement of diesel combustion systems by facilitating fuel air mixing rate via an increase in the fuel injection rate is explored. After reviewing relevant aspects of fuel air mixing and developing a parameter to correlate experimental data, the discussion focuses on combustion system response to increased fuel injection rate. Experimental responses of selected diesel combustion systems are based on the use of research engines and production-type multicylinder diesel engines with a naturally aspirated or a turbocharged rating. The maximum useful rate (MUR) concept is defined as the value of the fuel injection rate above which there is no further reduction of the brake specific fuel consumption, smoke, or carbon monoxide values. This rate is an important feature of combustion systems and, by definition, is independent of changing legislative targets for fuel economy and emissions. Data on mixing patterns of direct injection (DI) and indirect injection (IDI) engines, MUR values for different engines, optimum fuel injection rate, and computer model calculations of fuel economy show there are marked differences in the response of the combustion system to an increase in the fuel injection rate for swirl-type DI diesel engines. This is probably due to differing degrees of liquid fuel impingement on combustion chamber walls, resulting from various air inlet ports, air motion, and corresponding best nozzle configuration. For non-impingement conditions, there is a maximum useful injection rate beyond which no further reductions of smoke and carbon monoxide occur while nitrous oxides continue to increase. For engines operating with impingement, MUR values are reduced. The overall optimum injection rate for practical applications is less than the MUR and is a complex function of targets for gaseous and noise emissions and the response of the combustion system to fuel injection rate and fuel injection timing. Computer model calculations show that the achievement of short burn times to improve engine cycle efficiency introduces a penalty of increased convective heat loss as the rate of fuel air mixing is increased. Calculations also indicate relative cycle efficiencies to be expected in the high swirl mixing system of the IDI engine, the conventional swirl DI engine, and an adiabatic engine. In practice, low injection rates must be used to satisfy emission and other requirements. Engines with a high swirl rate and impingement give superior retardability for normal injection rates.

TWO WAYS TO BOOST A LIGHT DUTY DIESEL

Because light-duty diesels are often criticized for their poor specific power, boosting is proposed to improve performance, fuel consumption, noise, and emissions. The naturally-aspirated light-duty diesel is an attractive alternative to the gasoline engine because of its inherently better economy. It suffers considerably when compared to the gasoline engine, however, due to its poor specific power output. In addition to the best-known device for boosting diesel engines, the turbocharger, is another device, the pressure wave supercharger. Tests were conducted in which a turbocharger and a pressure wave supercharger (Comprex) were applied to the same light-duty vehicle to compare relative merits of the two systems. The Opel Rekord 2100D was the test vehicle, and a 1977 car equipped with a standard manual transmission served as the baseline vehicle. Measurements were made of acceleration time, gaseous emissions, fuel economy, and noise levels. Various other measurements, such as mechanical loading, thermal loading, and durability, were also carried out. The turbocharger enabled the diesel to give performance similar to its gasoline equivalent while retaining fuel economy and emission advantages. Problems of transient response and cost hinder its application. The Comprex permitted improved transient response and produced performance comparable to gasoline engines. Available machines remove initial problems associated with noise, installation, and drive. Cost, transient emission, and transient fuel consumption disadvantages need to be resolved. Both turbocharging and pressure wave supercharging systems can benefit from the use of ceramic components to reduce cost. Details on the test vehicle are appended.

THERMODYNAMIC EFFICIENCY EVALUATION OF AN INDIRECT INJECTION DIESEL ENGINE

Differences in fuel consumption between an 0.1 m bore indirect injection (IDI) diesel engine having a rated speed of 2,800 rev/min and a direct injection (DI) engine of similar specification were investigated. The objective was to identify, isolate, and quantify different sources of fuel efficiency loss. Consideration was given to such factors as increased heat transfer from the combustion system, gas pumping and resultant pressure difference between combustion chambers, different injection timing, and different fuel burning rate schedule. A mathematical model was derived to examine thermodynamic and fluid mechanic aspects of an IDI engine relative to a DI engine. This model was based on a two-zone system (main and prechamber), and experimentally-derived heat release schedules were used for the 0.1 m bore engine with a Ricardo Comet Vb prechamber. Principal loss sources, in order of importance, were a difference in the heat release rate schedule, increased heat transfer loss, later injection timing, and gas pumping through the connecting passage. At full load, 2,200 rev/min with representative injection timings for IDI and DI engines, the superiority of the DI engine amounted to 14% in terms of thermal efficiency. Additional study of airflow, fuel injection, air-fuel mixing, and combustion in main chambers and prechambers is recommended. Information on engine specifications and instruments used in the investigation is appended.

TURBULENT AIR FLOW IN THE COMBUSTION BOWL OF A D. I. [DIRECT INJECTION] DIESEL ENGINE AND ITS EFFECT ON ENGINE PERFORMANCE

The in-cylinder flow pattern of a direct injection (DI) diesel engine under motored conditions and its effect on engine performance when using different intake port designs were studied. Hot wire anemometry was utilized to analyze three different inlet port designs having the same swirl number (two helical ports and one tangential port). The flow investigation and engine tests were carried out at a typical compression ratio of 18:1 using a standard combustion bowl in the piston and produceable inlet ports. Motoring conditions in flow measurements covered the speed range from 1,100 to 2,400 rpm. Using probes located on the piston, a two-dimensional flow field including turbulence was established throughout the entire cycle. In-parallel engine tests were conducted with the ports in question to obtain performance, smoke, and gaseous emission data and to link engine test data with in-cylinder flow data. Certain air motion characteristics within the bowl were essential for the magnitude of exhaust smoke and for combustion efficiency (fuel economy). Smoke was mainly controlled by velocity and turbulence in the center of the combustion bowl. Combustion efficiency was primarily controlled by the tangential velocity (local swirl number) on the periphery of the combustion bowl. Helical ports generally exhibited quantitatively higher in-cylinder flow parameters at lower and higher engine speeds than the tangential port. Procedural aspects of the study are described in appendixes.

POWERTRAIN MATCHING FOR BETTER FUEL ECONOMY

Techniques for identifying fuel economy opportunities of powertrain matching are described. Federal Corporate Average Fuel Economy (CAFE) standards requiring an industrywide improvement of 53% between 1978 and 1985 pose a formidable task for the automotive industry, compounded by increasingly stringent emission standards. To meet the challenge, efforts are being concentrated in the following areas: vehicle/engine downsizing; improvements in powertrain component efficiencies; improvements in vehicle aerodynamics and rolling resistance; and powertrain matching. Powertrain matching tasks can generally be accomplished by vehicle/component testing (combining past experience with an iterative test program), computer simulatio (utilizing semiempirical mathematical models of vehicle and powertraining components to project fuel economy, performance, and emission tradeoffs), and computer simulation/vehicl testing (using computer modeling to screen alternatives to be evaluated during a vehicle/component test program). Fuel economy opportunities due to better powertrain matching are discussed, including optimum engine sizing, torque converte matching, transmission gear ratio spacing and shift schedulin axle ratio, and vehicle weight effect. An emission projectio technique based on time weighted engine speed/load point generated by experiment or analytical models is used to quantif fuel economy and emission tradeoffs. Recommendations to im prove the flexibility of computer models concern the development of a user-oriented engine model, a generalized cold start model, a tire dynamics model, and a drivetrain dynamics model.

REVIEW OF THE AUTOMOTIVE TORQUE CONVERTER

Fluid dynamic investigations were performed on a three-element automotive torque converter using computer solutions successfully applied in the design of gas turbines. With the aid of numerical solutions, surface velocities were computed along the reactor blade based on a two-dimensional flow field. These velocities were computed for an existing reactor blade and a proposed blade with a shortened axial chord. The reduced chord was intended for a more compact coverter circuit design. Diffusion factors and exit fluid angles of the short chord design were maintained within limits of the existing long chord design. Based on an approximation of the three-dimensional flow field, a computer program for the design of centrifugal impellers was modified for application to impellers with axial flow discharge, such as used in converter circuits. Results indicated the presence of negative and highly nonuniform velocities in the impeller. If negative velocities or backflows can be removed and more uniform velocity gradients maintained, higher energy efficiency should result. The use of gradually curved blading and recontoured shell and core shrouds are suggested as areas for further study.

DESIGN AND DEVELOPMENT OF A SINGLE RAIL SHIFT OVERDRIVE (SROD) MANUAL TRANSMISSION

The single-rail shift overdrive (SROD) four-speed manual transmission was designed to incorporate reliability and durability characteristics of a totally enclosed, nonadjusting single-rail shift mechanism while maintaining the conventional four-speed shift pattern. An additional objective was to optimize fuel economy with 3.3-liter, 4.1-liter, and 5-liter engines while maintaining acceptable vehicle performance and emission levels. Test vehicles were a Fairmont, Zephyr, Mustang, Capri, Granada, and Monarch (model year 1979). Design studies were conducted to determine the range of gear ratios possible and bearing loads. Extensive tests were made to assure engineering acceptance and customer satisfaction and reliability. These tests concerned high mileage proving ground durability, vehicle shift cycle durability, hot rod shifting, driveline impact and shock, dynamometer fatigue, powertrain bending and resonant frequency analysis, noise, shift efforts, gradeability and drivability, temperature and lubrication compatibility, and satisfaction of government restrictions and safety standards. A three-phase testing approach was successfully implemented to launch the SROD transmission. Supplier production problems were minimized, vehicle assembly plant installations were practically faultless, and customer approval of the transmission's function was acceptable. Procedures used to attain design objectives and satisfy performance requirements are detailed.

NEW 7.5- AND 8.5-INCH FORD AXLES FOR 1979

Two new axles for the 1979 model year and beyond have been developed by the Ford Motor Company to improve fuel efficiency and performance. In addition to fuel efficiency and performance benefits, advantages of the axles are improved reliability, manufacturing flexibility, complexity reduction, common axle ratios, and low ratio capability. Referred to as the 7.5-inch axle and the 8.5-inch axle, both are designed to be interchangeable where torque capacity permits. They share the following design features: cast center sections with cast upper control arm bosses for four-link suspension; cast iron shims and automatic selection equipment; tube assemblies with S-shaped suspension brackets for lower control arm and shock absorber mounting; circular companion flange; form-in-place cover gasket; and axle ratio capacity of 2.06:1 to 3.55:1 on the 7.5-inch axle and 2.26:1 to 4.10:1 on the 8.5-inch axle. The cast center axles, introduced in Ford and Mercury full-size cars, represent a major achievement in fuel efficiency. They are lightweight and reliable and offer improvements in manufacturing flexibility and complexity. A detailed description of axle design, accompanied by illustrations, is presented. Results of the axle design verification program are reported.

EVALUATION OF THE FLYWHEEL DRIVE CONCEPT FOR PASSENGER VEHICLES

Automobile flywheel energy storage and drive systems were the focus of a 4-year research effort to improve city gasoline mileage and performance with no degradation in emission standards. Problems arise in the automotive application of a flywheel to manage energy between a prime mover and a load. Flywheel energy management propulsion (FEMP) concepts indicate energy from passenger vehicle engines can be produced using an auxiliary energy storage device such as a flywheel to store excess energy not required to drive the vehicle. When the energy store is full, the engine can be decoupled from the driveshaft which is propelled by stored energy. The FEMP system is useful only for urban operation. Experimental study of flywheel concepts at the University of Wisconsin were based on two computer simulation techniques: continuous numerical integration where a driving cycle was subdivided into time increments of 0.1 second or less and variables (energy loss, fuel consumption, and distance traveled) were derived from totaling incremental values; and a driveshaft torque-speed matrix where a table was developed for each driving cycle to give the amount of time spent at various driveshaft-speed-torque conditions. In an experimental flywheel car, a 2.3-liter 4-cylinder Ford Pinto with a manual shift transmission, the engine on-off parameter was controlled by the driver. Most FEMP system losses during the city driving cycle were produced by the continuously variable transmission. The experimental car demonstrated a 50% mileage improvement over a corresponding production vehicle. It is concluded that FEMP concepts essentially involve a vehicle's transmission, where improvements can greatly enhance fuel economy. With continued research, gains of 100% appear feasible. The theory of flywheel energy management concepts is discussed.

PLANNING FOR AUTOMOTIVE ELECTRONIC INSTRUMENTATION

Factors to consider in developing automotive electronic instrumentation products are discussed, with reference to marketing study findings. Defining future market size, growth, competitive position, and effect on existing products is one of the electronic planner's most difficult tasks. The stage for automotive electronic instrumentation has been set by electronic calculators and digital watches in the home consumer market. Widespread acceptance of these products by the public, coupled with price reductions after introduction, has led to a significant growth market. As new vehicles are downsized and less reliant on styling changes, electronic instrumentation will play a greater role in enchancing the competitive posture of vehicles. In planning for automotive electronic instrumentation products, consideration must be given to such factors as the existence of a market, product variable costs, investment costs, reliability, human parameters, and regulatory requirements. Automotive electronic instrumentation product offerings in the United States and Europe are noted.

THE SEARCH FOR A NEW KIND OF CAR. PRESIDENT CALLS AUTO-MAKERS TO WHITE HOUSE FOR MEETING

Automobile technology was the topic of a May 1979 White House meeting attended by government officials and automobile manufacturers. Representatives of Ford Motor Co., American Motors Corp., General Motors Corp., and Chrysler Corp., were present, along with President Carter, Secretary of Transportation Brock Adams, Secretary of Energy James Schlesinger, and other Federal officials and White House aides. The meeting primarily focused on transportation and energy and the importance of inventing a car that will use less gasoline. President Carter indicated that government and the automobile industry should collaborate in the formation of a research strategy. Secretary Adams discussed safety and energy features of two new research safety vehicles and reported on his trip to Belgrade, Yugoslavia, where he spoke to European ministers of transport. A report cited at the meeting, prepared by DOT'S Transportation Systems Center in Cambridge, Mass., identified seven areas with the greatest potential for advanced automobile technology: thermodynamics, combustion, and fluid flow; energy storage; engine-fuel interactions; materials science and processing; control systems; structures; and friction and wear.

1978 ACCIDENT DATA. TRAFFIC VOLUMES AND MILEAGE ON THE STATE HIGHWAY SYSTEM BY ROUTE, COUNTY AND MUNICIPALITY [NEW JERSEY]

New Jersey highway accident statistics for 1978 are presented. Tabulated data categorize accidents according to number of highway lanes, traffic volume, and mileage. Statistics are presented concerning total accidents, injury accidents, fatal accidents, number of injuries, and fatalities. Detailed tables provide information on type of highway (2, 3, 4, or 6 lanes; divided, no control of access; divided, full control of access; and variable, change in highway type within municipality). Accidents are reported by route, county, and municipality.

STUDIES OF ROADSIDE HAZARDS FOR PROJECTING FATAL CRASH SITES

A survey was made of road curvature, superelevation, gradient, and number and distance from the roadway of roadside hazards at 300 sites of fatal crashes into fixed objects, and at 300 comparison sites 1.6 km (1 mi) from each accident site in Georgia. More than 26% of fatal crash sites and only 8% of comparison sites had road curvature greater than 6 degrees combined with downhill gradient of -2% or less at or approaching the sites. Fifty percent of fatal crash sites and only 23% of comparison sites were at or near curves greater than 6 degrees irrespective of gradient. A state study found that only 22% of roadways in Georgia had curvatures of more than 5.5 degrees. Nonlocal roads accounted for 83% of the fatal crashes into fixed objects but comprised only 33% of the roads in the state. In 98% of the cases, objects struck were within 15 m (50 ft) of the pavement edge. Top priority should be given to modifications of roadside hazards on and near curves greater than 6 degrees, particularly those on nonlocal roads where the downhill grades are -2% or less.

EVALUATION OF ALCOHOLISM TREATMENT PROGRAMS FOR DRINKING DRIVERS

In 1971, the National Institute on Alcohol Abuse and Alcoholism (NIAAA) initiated a program to support centers designed to extend and improve the treatment and rehabilitation services available for problem drinking drivers. These centers were located at selected Alcohol Safety Action Program (ASAP) sites of the National Highway Traffic Safety Administration. A preliminary evaluation is made of the clients provided services at these sites. Demographic data, various drinking-related measures, a self-esteem index, and financial and employment status variables were obtained for the large sample of clients who received service from May 1973 through Mar 1974. Clients were classified into five groups and were compared: DWI (driving while intoxicated) probation, DWI school, DWI non-AC (alcoholism center) treatment, DWI AC treatment, and non-ASAP. The results indicated that for all programs for which follow-up data were obtained the percentage of clients who abstained from alcohol increased, the amount of absolute alcohol consumed per day decreased, behavioral impairment caused by drinking decreased, and self-esteem improved. Although a trend for an increase in financial status was observed, further follow-up study is needed for confirmation. Treatment outcome was more successful with clients showing less involvement with alcohol, which supports the NIAAA premise that is the basis for its support of ASAP programs: ASAP programs include a large number of individuals for whom early intervention into their alcohol problems would be worthwhile.

ECONOMIC ANALYSIS OF ALCOHOL SAFETY COUNTERMEASURES

This analysis determined the potential for successful implementation of each of seven alcohol countermeasures in terms of cost effectiveness and provided baseline information for the National Hwy. Traffic Safety Administration to use in research fund allocation for the development of countermeasures. The countermeasures included the sober pill, self-tester, evidential roadside tester, noncooperative breath tester, alcohol safety interlock system, continuous monitoring device, and operating-time recorder. A set of benefit/cost ratios was calculated for each, and sensitivity analyses were performed on the crucial assumptions and key elements of costs and benefits to test their impact on the ratios. The potential for successful implementation was assessed on the basis of the benefit/cost ratios, and social, technological, and legal feasibility. All seven countermeasures are either in the conceptual or experimental testing stages of development. The sober pill would be cost-effective if single doses cost 25 cents and if it effectively reduced BAC (blood alcohol concentration) level by 0.04% to 0.05%. Self-testers would be cost-effective if users did not drive 75% of the time that their BAC levels were 0.10 or greater. Evidential roadside and noncooperative breath testers would be cost-effective if they deterred 1% to 2% of trips by persons with a BAC of 0.10 or greater. The alcohol safety interlock system would be cost-effective if a device could be developed that had at least 50% effectiveness at a 0.10 or greater BAC, was tamperproof, and required minimal maintenance and installation cost. The continuous monitoring device would be cost-effective if drivers who have the device abide by the warning 50% to 60% of the time. The operating-time recorder would be cost-effective if it were 50% to 60% effective in eliminating trips made with a 0.10 or greater BAC during restricted hours.

ADMINISTRATIVE ADJUDICATION OF DRIVING-WHILE-INTOXICATED OFFENSES

Recent studies have shown that the enactment of strong laws and the stringent enforcement of those laws by the courts and police have not been empirically proved as effective measures for reducing accidents caused by excessive drinking and driving. A multifaced alcohol countermeasure program is needed to significantly reduce the number of deaths and serious injuries caused by alcohol-related crashes. The problem of drinking and driving can be brought to a manageable level if all of the facilities and services available to states and communities are used. The concept of administrative adjudication, the handling of traffic offenses through an administrative or quasi-judicial approach, has gained widespread attention and is in use in some jurisdictions. The administrative adjudication of first-offense drivers charged with driving while intoxicated would increase the arrests and convictions of drunken drivers, and would lead to early identification of existing or potential alcoholics, with the possibility of leading them to proper treatment or education programs.

EVALUATION OF THE HALO EFFECT IN SPEED DETECTION AND ENFORCEMENT (ABRIDGEMENT)

A study was undertaken to determine if specific treatments on a section of NC-55, a two-lane, rural roadway in North Carolina, could extend the halo effect (i.e. the effect on driver behavior beyond the point and time when enforcement is applied). A VSI (visual speed indicator) sign display, a control treatment in which the VSI sign was covered and no patrol unit was present, and three other static (radar device) enforcement techniques (speed-check zone, parked patrol car, and speed enforcement scene) were utilized. It was found that the use of the three enforcement techniques substantially and significantly reduced the mean, median, and 85th percentile speeds in the vicinity of the enforcement unit. All three techniques significantly reduced (almost eliminated) the percentage of vehicles traveling faster than 88.5 kph (55 mph) and also increased the percentage of vehicles traveling slower than 72.4 kph (45 mph). All three techniques reduced the variability of speeds at the enforcement location. The VSI sign had no significant effect on vehicle speed and was no substitute for actual enforcement activity. The halo effect began to disappear 305 m (1000 ft) past the enforcement treatment and was completely gone at a point 3.2 km (2 mi) downstream.

ANALYSIS OF THE RELATION OF ACCIDENTS AND THE 88-KM/H (55-MPH) SPEED LIMIT ON ARIZONA HIGHWAYS (ABRIDGMENT)

A study was undertaken to determine whether there was a causal relationship between the reduced number of traffic accidents and fatalities in Arizona in 1974 and the 88 kph (55 mph) speed limit. Every accident occurring on segments of Interstate, U.S., and state highways that had previously posted maximum speed limits in excess of 55 mph was analyzed. It was found that driver and vehicle characteristics did not affect the 1974 reduction in fatal accidents, but that traffic-related environmental factors influencing driving conditions and travel patterns changed between 1973 and 1974. All categories of accidents decreased in 1974. The number of fatal accidents and the number of total accidents had the highest relative decrease on Interstate highways. Interstate highways that had speed limits of 120 kph (75 mph) in 1973 had the largest decrease in total accident rates. Non-Interstate highways that had speed limits of 104 kph (65 mph) in 1973 had substantially smaller decreases in injury, property-damage-only (PDO), and total accident rates than those on Interstate highways. It is concluded that the reductions in fatal, injury, PDO, and total accident rates (removal of the effect of travel variations) are attributable to the reduction in speeds and the greater uniformity of speeds within the traffic stream. The reduction of fatal accidents in the study accounted for over 92% of the total reduction in statewide fatal traffic accidents in 1974.

RECENT TRENDS IN VAN AND SMALL TRUCK SAFETY

The dramatic increase in the use of pickup trucks and vans prompts an inquiry into vehicle performance and safety. Because pickups and vans do not belong to the passenger car category, they are exempt from many Federal safety regulations governing automobile components. The annual production of pickups increased by 32.5% between 1970 and 1975. There was a 62.7% increase from 1976 to 1977. Corresponding figures for vans were 122% (1970-1975) and 37% (1976-1977). Vehicle production data were combined with scrap rate information to estimate the number of pickups and vans in use. Related accident involvement and fatalities were obtained from the Fatal Accident Reporting System for 1977. Compared to passenger cars, pickups have a considerably higher accident involvement rate but only a slightly higher fatality rate. Vans are involved in accidents nearly as often as passenger cars but have a lower fatality rate. These variations are probably due to different vehicle use patterns. Analysis of two-vehicle collisions reveals that pickups and vans seem to perform somewhat better than passenger cars on a scale designed to reflect gross safety aspects. Vans appear to be associated with a disproportionate number of single-vehicle accidents involving pedestrians and bicycles, due to possible heavier use in densely populated urban areas; pickups are more often used in rural areas. Although data indicate that pickups and vans are not less safe than passenger cars, additional study is warranted to resolve issues regarding use patterns and vehicle occupant protection.

IMPROVING ANTI-ROLL PROPERTIES OF SEMITRAILERS, ROAD TRACTORS, AND HEAVY TRUCKS

Eliminating the free play in leaf spring assemblies is one way of significantly reducing the rollover potential of tractor-semitrailers. The rollover threshold can be reduced by 10% to 15%, which is significant because the lash space permitting free play is present in suspensions of most U.S. semitrailers and in many rear axle assemblies of heavy trucks and road tractors. Dynamic tests and computer simulations indicate that suspension free play contributes to roll instability when a vehicle changes direction quickly enough to unload springs on one side of the vehicle. Free play can be inexpensively eliminated or greatly reduced by installing a bolt beneath the leaf spring or by filling the lash space beneath the spring with a rubber bushing. It is estimated that a 15% improvement in the roll stability of tractor-semitrailers can potentially reduce the incidence of rollovers by 40%. While the total number of heavy vehicle rollovers per year is not high, such accidents often pose serious safety hazards for other vehicles. The free play elimination technique is illustrated.

THE FARS [FATAL ACCIDENT REPORTING SYSTEM] DATA AND SIDE-IMPACT COLLISIONS

Side impact collisions were analyzed using information extracted from the National Highway Traffic Safety Administration's 1977 Fatal Accident Reporting System (FARS) files and information from the National Crash Severity Study (NCSS). The comparative study was designed to assess the value of FARS data in accurately depicting a particular type of accident. In 1977, FARS data showed 7,902 occupants in passenger car accidents involving side damage. These accidents were classified as rollovers, two-vehicle collisions, and single-vehicle collisions. Statistics were obtained on the number of in-vehicle fatalities, the mean age of fatally-injured occupants, the percent of male occupant fatalities, the mean vehicle weight, and the percent of occupant fatalities using some form of restraint system. Data in the NCSS were obtained from a sample of towaway passenger car accidents in the 38 contiguous States. For passenger cars struck in the side, the total number of occupants in NCSS regions was 13,302. The population variable was used to extrapolate information from NCSS accident records in estimating national figures. An expected fatality rate was calculated, fatalities from the FARS divided by total estimated crash occupants from the NCSS for each crash configuration of interest. The overall fatality rate for side impact collisions was calculated as 1.45 fatalities per 100 crash occupants. Highest fatality rates involved cars struck by trucks or fixed objects; lowest fatality rates involved cars struck by other cars. Occupants of cars struck in the side by trucks or fixed objects constituted 30% of all occupants in side impact collisions but 50% of all fatalities. Side door strength is important in preventing fatal injuries by minimizing intrusion into the passenger compartment. This anti-intrusion measure is most effective when a car is struck by another car, but even the best side door strength can eliminate only a portion of fatalities involving vehicles hit by large trucks or fixed objects.

MVMA (MOTOR VEHICLE MANUFACTURERS ASSOCIATION) TWO-DIMENSIONAL CRASH VICTIM SIMULATION TUTORIAL SYSTEM: SELF-STUDY GUIDE. FINAL REPORT

The Motor Vehicle Manufacturers Assoc. Two-Dimensional Crash Victim Simulator is a mathematical model used for predicting occupant dynamics in a crash environment. The computer model is large and complex. Its many options and features provide the automotive safety engineer considerable flexibility in defining a crash event but at the same time impose considerable demands for specification of input data. As a means of facilitating learning to use the model, the Tutorial System combines a Self-Study Guide and an Audio-Visual Program. Both are divided into 13 segments, called "modules", each of which deals with the data requirements of a set of related model features. Each audiovisual module consists of 35 mm slides and approximately 20 minutes of narration on a tape cassette. Module topics include an introduction, the body linkage, neck and shoulder models, contact surfaces attached to the occupant and those attached to the vehicle, generation of occupant contact profiles, occupant positioning in the vehicle, crash deceleration profiles and head applied forces, belt and air bag restraint systems, energy-absorbing steering columns, model operation, and example crash simulations. Tutorial System documentation is in two volumes. The Self-Study Guide consists of text, illustrations, and example problems. The Audio-Visual Program includes the narration text and figures used for the 35 mm slides.

EEG [ELECTROENCEPHALOGRAM] ALPHA CORRELATES OF ALCOHOL CONSUMPTION IN SMOKERS AND NONSMOKERS. EFFECTS OF SMOKING AND SMOKING DEPRIVATION

Tonic activity of smokers and nonsmokers was investigated by correlating alpha frequencies of electroencephalogram (EEG) activity under conditions of smoking and smoking deprivation with alcohol consumption. The primary interest was in dominant alpha frequency as a measure of cortical response to alcohol, but alpha amplitude was also examined to evaluate the effect of smoking on alcohol-induced changes in EEG'S. Subjects included 35 male university students, nine of whom were nonsmokers. Fourteen smokers, assigned to the smoking deprivation condition, were required to abstain from smoking for 15-18 hours. The remaining subjects were permitted to smoke in their usual manner. Each subject participated in alcohol and nonalcohol sessions spaced seven days apart and conducted at the same time of day. Alcohol (95% Analar-grade ethanol) at a dose level of 0.65 g per kg of body weight, diluted to a 20% solution, produced a blood alcohol concentration (BAC) ranging from 0.07% to 0.08% about 30-50 minutes after ingestion. Smoking in both alcohol and nonalcohol sessions was controlled at a constant inhalation rate of once every 30 seconds during four 5-minute periods. Tobacco smoking prior to and/or during alcohol consumption counteracted the alcohol-induced slowing of alpha frequencies observed in nonsmokers and deprived smokers. Alpha amplitude did not differentiate among nonsmokers, deprived smokers, and nondeprived smokers, nor did alpha amplitude exhibit changes immediately after smoking. Alcohol and nonalcohol sessions showed no significant difference in alpha amplitude change scores. Failure to find any significant tobacco-induced BAC alterations suggests that the observed alcohol-tobacco antagonism occurs in the central nervous system. Further study of both tonic and phasic aspects of physiological activity is recommended to clarify alcohol-tobacco interactions and the importance of tobacco in alcohol consumption.

COMPARISON OF FUEL ECONOMY AND EMISSIONS FOR DIESEL AND GASOLINE POWERED TAXICABS. FINAL REPORT

Sixty-six diesel-powered taxicabs and an equal number of gasoline-powered taxicabs were operated for 120,000 miles in New York City to compare fuel economy and exhaust emissions. Actual road records of fuel use were analyzed. For a select group of taxicabs, laboratory measurements of fuel economy and exhaust emissions were obtained. Fuel economy was assessed based on accumulated mileage and fuel use per shift. Data for fuel economy and exhaust emissions were also derived from dynamometer testing in accordance with the Environmental Protection Agency's Federal Test Procedure and from computer simulations of the Modified Urban Cycle (average speed of 10.5 mph instead of 11 mph). Flat operating conditions were similar for diesel and gasoline taxicabs. Comparative analysis indicated diesel taxicabs had 50% better fuel economy than gasoline taxicabs on the road and that diesel exhaust emissions (hydrocarbons, carbon monoxide, and nitrogen oxides) were lower than gasoline exhaust emissions. Emissions from gasoline taxicabs increased appreciably with vehicle age, while diesel emissions did not degrade significantly. Measured diesel particulates were at a low level, as demonstrated by opacity readings of the exhaust stream. Information on the structure of magnetic tape records used in data collection is appended.

DEATH AND INJURY ROAD ACCIDENTS IN NORTHERN IRELAND 1978

Statistical data are compiled on fatal and injury-producing traffic accidents in Northern Ireland in 1978, including accident causes and culpable road users. These accidents increased by 2.2% (a total of 5437) and casualties by 2.9% (a total of 8080), but fatalities decreased by 18.8% (355 in 1977 to 288 in 1978). Motorcycle casualties decreased 7.6% from 1977. The number of motor vehicles registered during 1978 increased by 3% to almost 430,000 vehicles. During 1978, one person was killed in every 19 accidents; the 1977 ratio was 1:15. The 288 fatalities occurred in 267 accidents; the principal causal factors were as follows: drivers, motorcyclists, pedalcyclists at fault (171 accidents); pedestrian at fault (71); road and weather conditions, animals, other obstructions, and passengers at fault (15); and defective vehicles or equipment (10). The most common violations by the drivers and cyclists were excessive speed for conditions, and driving under the influence of alcohol or other drugs. The most common pedestrian factors were disregard of traffic when crossing the roadway, and being under the influence of alcohol or other drugs. Defective brakes or tires were the most common vehicle defects. Ice, frost, or snow were the most common environmental factors implicated in these fatal traffic accidents.

GUIDE TO HIGH SPEED PATROL CAR TIRES (LAW ENFORCEMENT EQUIPMENT TECHNOLOGY)

This law enforcement equipment guide contains information on the selection and maintenance of high-speed patrol car tires. Pursuit tires, i.e., those certified for speeds up to 125 mph (200 km/hr), represent a significant portion of a police department's transportation budget. Properly selected and maintained tires can save money and improve the safety and performance of patrol cars. Tire selection and maintenance guidelines are provided, focusing on maximum safety, tire life, and performance. Particular attention is paid to application factors (type of road, pursuit driving, tire maintenance, hazard exposure, type of tire, tire mileage, snow tires, and radials versus snow tires); technical factors (construction, tire markings and materials, use of chains, and tires and gasoline mileage); cost and performance factors, (braking traction, cornering traction, driving traction, and endurance and tread wear); operational factors (mounting tires on wheels, inflation pressure, radial run-out, balancing and alignment, safety precautions, break-in, inflation and loading, road conditions, driver habits, and mechanical condition of vehicle); and maintenance factors (inflation checks, tire rotation, detection of faults, mixing and matching tires, position of least worn tires, abnormal tread wear, and repairs and servicing). Data on tire interchangeability, load and inflation, and mixing, and on Federal regulations pertinent to vehicle tires, are appended.

WEIGH-IN-MOTION INSTRUMENTATION [TRUCK WEIGHT]. FINAL REPORT

A system is described for surveying truck gross and axle weights in an undetected manner with signals from traffic sensors and instrumented strain gauges on bridge girders. A derived weight prediction algorithm filters out the dynamic components of bridge response and obtains the equivalent static axle weights by a least square error minimization. Accurate predictions require the truck dimensions and velocity obtained from traffic sensors. Signals from the traffic and strain transducers go directly to a minicomputer located in an instrument van underneath the bridge for digitizing and placing on a magnetic tape. An operator is needed to press a button to alert the system to the number of axles of an approaching truck. At the present developmental stage, the system is configured so that the magnetic tape is processed in the laboratory using a digital computer. Details discussed include field operation and installation, theoretical considerations, computer programs, test results, and further modifications of the system to permit the field minicomputer to predict weight in real time and to allow routine system use by highway departments. Documentation manuals have been prepared with more detailed descriptions of the use of the system and its fabrication and assembly.

COMPARISON OF ORGANIZATIONAL AND OPERATIONAL ASPECTS OF FOUR VANPOOL DEMONSTRATION PROJECTS. FINAL REPORT

Four demonstration projects involving vanpooling, currently being sponsored by the Dept. of Transportation Service and Methods Demonstration Prog., are described and compared in terms of organization and operation. The projects in San Francisco, Calif., Minneapolis, Minn., Knoxville, Tenn., and Norfolk, Va., all involve third-party providers and multiple employment locations. A comparison is made of management and administration, target group focus, marketing procedures, driver and rider application and selection procedures, van acquisition and provision arrangements, and financial aspects, such as cost structures, driver lease fees, passenger fares, and project funding.

TRAFFIC CONTROL DEVICES, VISIBILITY, AND GEOMETRICS

Traffic signs and signals, visibility, and safety are considered in this compilation of 17 papers. The papers cover such topics as a prototype delineation system for installation on concrete median barriers, yellow-on-brown road signs, nonsignalized traffic control at low-volume intersections, signing warrants for nonservice facilities, sign performance under dew and frost conditions, relation between sign luminance and specific intensity of reflective materials, daytime high-visibility aids for motorcyclists, signalization of high-speed isolated intersections, relation between lighting parameters and transportation performance, driver vision, roadside hazards, two-way left turn lanes, selection of median treatments for arterial highways, relation of highway design consistency and systematic design to highway safety, lateral displacement phenomena, and accidents (two-lane rural roadside, urban utility pole).

EVALUATION OF DELINEATION SYSTEMS FOR THE NEW JERSEY BARRIER

A prototype delineation system for installation on the New Jersey type of concrete median barrier is described. In system development, environmental factors affecting delineator performance were identified. The relation was assessed between environmental factors (weather conditions, dirt accumulation, wear from windblown particles, glare from opposing traffic, and destructive forces) and experimental variables (type of reflective device, vertical position on barrier, and mounting materials and techniques). As weathering or exposure time increased, the relative brightness of one reflector with a convex glass lens increased to the point that it was rated as the brightest after two winters of exposure. The top-side vertical position showed slightly less reduction in reflectivity than the bottom-side vertical position. It was hypothesized that dirt and debris channeled down the side of the barrier by natural wind or the slipstream wind of vehicles accounted for the much greater wear and dirt covering on side-mounted reflectors. Visibility of reflective devices improved during wet nighttime conditions. Delineator effectiveness diminished when there was opposing headlight glare. The most durable mounting technique was a butyl adhesive pad attached to a low-profile marker. Further research to explore the role of delineation systems in highway safety is recommended.

EVALUATION OF YELLOW-ON-BROWN ROAD SIGNS FOR THE ADIRONDACK PARK (ABRIDGMENT)

Aesthetic, visibility, and legibility factors associated with the use of yellow-on-brown information signs in New York's Adirondack Park were studied. Signs were installed on an experimental basis along a reconstructed State highway segment in 1976. The aesthetic appraisal consisted of photographic documentation and a driver opinion survey. Actual test signs were selected for legibility and visibility evaluation. Study findings revealed that driver parameters of age, sex, driving experience, and visual acuity were not related to differences in performance among sign background colors (brown, blue, and green). The sample included few inexperienced drivers and few over 60 years of age. About 80% of drivers favored the use of yellow-on-brown signs, and color photographs confirmed the importance of background color in sign visibility. All sign-color combinations were legible beyond the accepted standard of 50 ft/in (6 m/cm) for letter height during daylight. Differences in legibility and visibility among colors were small but statistically significant in some cases. It is concluded that widespread use of yellow-on-brown information signs can enhance the appearance of Adirondack Park highways without affecting highway safety or motorist convenience. In 1978, the Federal Hwy. Administration agreed to a variance permitting yellow-on-brown highway signs in Adirondack Park.

COMPREHENSIVE EVALUATION OF NONSIGNALIZED CONTROL AT LOW-VOLUME INTERSECTIONS (ABRIDGMENT)

The most efficient signing policy for traffic flow through low-volume unsignalized intersections was investigated. Computer algorithms were used to study fuel consumption, exhaust emissions, and travel time. Probability of conflict techniques, used in conjunction with accident records, supported the safety portion of analysis. Two validated simulation aides were required, a traffic model sufficiently detailed to reproduce flow characteristics of low-volume unsignalized intersections, and a program to process traffic simulation output on an individual vehicle basis and estimate fuel consumption and resulting emissions. The Environmental Protection Agency model for emissions (nitrogen oxides, hydrocarbons, carbon monoxide, and carbon dioxide) and the Urban Traffic Control Simulation model of the Federal Hwy. Administration permitted statistical comparisons. Gasoline use was a function of control type implemented at intersections.

Restrictive control caused a significant increase in carbon monoxide emission. A highly significant difference in minor street travel time or delay was demonstrated for different control types. Energy savings were attributed to a policy that emphasizes yield signs and no sign control rather than a policy of stop signs at low-volume intersections with adequate sight distance, and it was determined that few accidents can be expected to occur at typical low-volume intersections regardless of what form of control is installed.

SIGNING WARRANTS FOR NONSERVICE FACILITIES (ABRIDGMENT)

Warrants used by 49 States for nonservice facility signing on expressways and freeways were reviewed. The study was conducted in 1975-1976, and information on 14 types of nonservice facilities was requested (amusement parks, zoological or botanical parks, stadium sports facilities, colleges and universities, recreational or cultural facilities, airports, industrial areas, central business districts, bus terminals or stations, bus park-and-ride lots and carpool lots, rail terminals or stations, roll-collecting highways and bridges, health care facilities other than hospitals, and government facilities). States were asked whether they signed for each facility on expressways and freeways and whether they had any written warrants or criteria for this function. Of the 49 States, 46 indicated they made a distinction between the use of actual and categorical terms in the warrant process. Most warrants were of a specific or quantitative nature and were grouped according to the following facility criteria: location relative to the highway; level of activity; size or capacity; traffic generation; availability; ownership; public services and attraction value; population range of surrounding area; and placement and number of signs. Warrants should involve specific criteria. Major items of concern should be the first three criteria mentioned above and population of the surrounding area. Guidelines developed by the American Assoc. of State Hwy. Officials to facilitate traffic generator signing are presented.

PERFORMANCE OF SIGNS UNDER DEW AND FROST CONDITIONS (ABRIDGMENT)

The effect of dew and frost on the nighttime legibility of traffic signs in the central part of Kentucky was investigated. Thirty-one nights with observed natural dew or frost formation between 9:00 p.m. and midnight were selected to evaluate several possible combinations of retroreflective legend and background materials under headlight illumination. Test procedures varied according to prevailing atmospheric conditions. Observations and photographs were normally made at 1-hour intervals. Sign positions were interchanged (left to right) at the midpoint of the study. Under direct headlight illumination from 91.44 meters and with natural dew formation conditions at the sign face, the performance of encapsulated lens retroreflective sign materials was superior to that of enclosed lens materials and equal (for light dew) or superior (for heavy dew) to button copy. Under the same viewing conditions but under frost formation conditions, the performance of button copy was superior to that of other test materials. Viewed from a position laterally offset 1.8 meters from the light source, encapsulated lens materials and button copy were almost identical in performance under frost conditions. Viewed from greater lateral offset distances, all other test materials were superior to button copy under both dew and frost conditions. Button copy legends exhibited the most noticeable degradation in performance over time under dew and frost conditions, presumably due to aging (weathering) and/or accumulation of dirt film. Decreases in sign legibility and target value caused by dew and frost formation were more pronounced on plywood-backed sign panels than on plain aluminum panels. The performance of all combinations of sign materials appeared to be less affected by frost than by dew. Under normal atmospheric conditions and signing practices, it is estimated that 50% to 80% of adverse effects associated with dew and frost can be overcome by using encapsulated lens signing materials.

RELATION BETWEEN SIGN LUMINANCE AND SPECIFIC INTENSITY OF REFLECTIVE MATERIALS

A simple means of translation was explored to aid in the proper selection and application of materials where traffic sign luminance is desired. Determinations of nighttime sign luminance were made from the driver's eye position in a standard-sized passenger automobile with carefully selected normal headlamps. Measurements were made on a smooth tangent roadway using a laboratory telephotometer at distances of 600 and 300 feet. Reflective samples were mounted in typical sign positions, representing specific intensities in silver-white, yellow, orange, red, and green colors. The two observation angles common to most highway specifications, 0.2 and 0.5 degrees at -4 degree entrance angle, were used to determine a broad luminance span. Readings on the test road were correlated by linear regression. Resulting equations established the relation between sign luminance and the specific intensity of reflective materials according to distance, sign, and headlamp position. These equations permit the computation of sign luminance or specific intensity for any type of reflective sheeting.

EVALUATION OF DAYTIME HIGH-VISIBILITY AIDS FOR MOTORCYCLISTS

A survey of consumer attitudes toward such conspicuity aids for motorcyclists as jackets, vests, sleeves, and slipovers was conducted, and the effectiveness of conspicuity aids in facilitating motorcyclist detection was considered. Comments are tabulated on 19 options, as well as user ratings, chromaticity and unit cost. Many pieces of high visibility clothing had serious design problems and were strongly criticized by motorcyclists. Most fluorescent materials exhibited a strong tendency to lose both color and fluorescence in a relatively short time. The time taken to detect a motorcyclist wearing a conspicuous color was inversely related to the projected area of color. Neither the wearing of high visibility clothing nor the daytime use of headlights affected motorist gap-acceptance behavior.

SIGNALIZATION OF HIGH-SPEED, ISOLATED INTERSECTIONS

Various detector-controller designs for high-speed isolated traffic intersections were examined. At signalized intersections where approach speeds are 35 mph (56 km/hr) or higher, drivers face a so-called dilemma zone. If the yellow signal comes on while the driver is in this zone, the decision to stop may result in a rear-end collision or a sideswipe. The opposite decision, to go through the intersection, may produce a right-angle accident. For such an intersection, the traffic engineer needs to select a detector-controller configuration that detects an approaching vehicle before it enters the dilemma zone and adjusts the green signal to provide safe passage through the zone or to warn the vehicle upstream of the zone in time to provide adequate stopping distance. A new detector-controlled design is proposed, utilizing an actuated nonlocking controller, an 85-foot (25-meter) delayed-call loop detector at the stopline, and two extended-call detectors upstream to give protection to the dilemma zone. Knowledge of dilemma zone boundaries is reviewed. Detectors and controllers are classified, a taxonomy of detector-controller configurations is presented, and research data on the effectiveness of green extension systems are summarized.

RELATION BETWEEN LIGHTING PARAMETERS AND TRANSPORTATION PERFORMANCE

The relation is addressed between technical requirements for road traffic lighting (geometry and photometry) and functions of safety, speed, comfort, and cost, with emphasis on safety considerations. The chain between cost and effectiveness, i.e., transportation performance or accident reduction, is broken down into the elements of costs and related installation parameters on the supply side, and road traffic and transportation performance on the demand side. For good road lighting, the supply should equal or exceed the demand. In terms of existing vs. required conspicuity level, the supply should equal or exceed the demand. The supplied conspicuity level can be derived from installation parameters by well-established methods. A similar derivation of the required conspicuity level from traffic and transportation performance requires additional research. The traditional method, in which one or two standard visual tasks are postulated as representative of driving, is unsatisfactory and may cause erroneous results. Further detailed research on lighting parameters is recommended.

REANALYSIS OF CALIFORNIA DRIVER-VISION DATA: GENERAL FINDINGS (ABRIDGMENT)

The ability of vision tests to identify drivers likely to have traffic accidents is discussed. In 1967-1968, visual measurements involving 17,500 California drivers were made and the results were compared with 3-year driving records which included over 5,200 accidents. Findings revealed weak but statistically significant correlations between various vision scores and driving records. The best vision test for predicting accidents was the dynamic visual acuity test in which the observer had to resolve detail in a rapidly moving acuity target. By itself, however, this test was a poor predictor of a driver's accident rate. The ability of static visual acuity, dynamic visual acuity, low-light recognition threshold, glare recovery, and field of vision tests to identify drivers likely to have accidents, without paying an unacceptably high penalty in the rejection of good drivers, is questionable. Visual performance of older drivers may merely reflect their effective or phenomenal age, and another factor, such as deterioration of the brain's central processing capacity, may be the basic cause of increased accident rates. Improving visual performance may not improve a driver's accident rate. Even though a visual performance measure is not causally related to accident rate, its predictive power may still be valuable in screening or in establishing visual standards. Investigation of contrast sensitivity, movement perception, and hazard perception tests and other stimulus conditions for the potentially effective glare recovery test is recommended.

ROADSIDE HAZARD MODEL (ABRIDGMENT)

A study was designed to identify and quantify parameters associated with single-vehicle fixed-object accident severity and probability and to incorporate these parameters into a hazard model. Field surveys identified numerous hazardous objects adjacent to the roadway, including drainage facilities, traffic signal supports, and utility poles. The initial structure of the roadside hazard model incorporated seven mathematical terms: relative hazard of a particular object; normalizing constant; distance of an object from the road edge; prevailing speed of traffic; severity index associated with type of object; traffic volume; and geometric conditions. Parameters subsequently quantified in the model were distance, speed, severity index, traffic volume, and geometrics. A computer program was used to calculate a hazard index for 8,424 combinations of speed, object, distance, and geometric parameters in accordance with traffic volume. An examination of the top 150 hazard indexes for wide rural roads with an average daily traffic level of 8,000 vehicles revealed that 45% of entries had speeds of 88 km/hr. Vehicle location on the outside of curves was dominant. No objects more than three meters from the road edge appeared in the list of the 150 indexes, and most on the list were within 1.5 meters. Application of the hazard model to evaluate remedial actions and to rank hazards is discussed.

MACROSCOPIC MODELING OF TWO-LANE RURAL ROADSIDE ACCIDENTS

A macroscopic study of off-road accident, road, and traffic flow characteristics on the rural two-lane trunkline road system in Michigan was conducted to aid the Department of State Highways and Transportation in developing priority programs for roadside hazard improvement. Based on statewide accident data for the 1971-1974 period, a macroscopic modeling effort was initiated for 270 two-mile sections of homogeneous two-lane road with widely varying road and traffic conditions. Road data came primarily from an analysis of the department's photolog files. Multiplicative models for different groups of average daily traffic were developed in which restriction on passing sight distance, number and length of curves, and length of road exposed to obstacles were primary explanatory variables. These models, evolved dynamically with the aid of statistical computer programs, were tested for validity. They explained as much variance as would be expected assuming a Poisson accident frequency distribution. Study findings indicate that a small number of causal variables can be combined in a multiplicative model to explain variations in accident frequency on rural two-lane roads. Such a model is applicable to the identification of locations with a high probability of frequent off-road accidents, and of locations where additional factors may be at work and engineering study is needed.

TWO-WAY LEFT-TURN LANES: STATE-OF-THE-ART OVERVIEW AND IMPLEMENTATION GUIDE

Research was carried out to obtain information on continuous two-way left-turn median lanes and to evaluate the effectiveness of such lanes as an access control measure. A questionnaire was sent to transportation engineers; of 90 mailed out, 70 were returned from individuals in 36 states and one Canadian city. Primary areas of interest were the effect of the lanes on traffic safety and flow characteristics, and conditions conducive to lane installation. Respondents stated that two-way left-turn median lanes work well despite non-uniformity in signing and marking methods. There was uniform agreement that the lanes have excellent safety records; specifically, head-on collisions are extremely rare. It was concluded that lane effectiveness and public reaction depend on proper engineering. Attention should be paid to future access needs and through traffic volumes before the final selection of an access control method. A step-by-step decisionmaking strategy for the implementation of two-way left-turn median lanes is outlined.

SELECTION OF MEDIAN TREATMENTS FOR EXISTING ARTERIAL HIGHWAYS

A cost-benefit comparison of median treatments for arterial highways is reported that covers accident reduction, delay reduction, and construction cost. Median treatments represent an important means of reducing accidents and delay on urban arterial highways. Five common median treatments are two-way left-turn lanes, continuous left-turn lanes, alternating left-turn lanes, raised median dividers with left-turn deceleration lanes, and median barriers with no direct left-turn access. The result of comparative analysis is a selection guide for use by designers in determining the optimal median treatment for an arterial highway based on geometric and operational conditions. A table summarizes cost-benefit analysis findings in the form of a selection guide for median treatments and construction options.

HIGHWAY DESIGN CONSISTENCY AND SYSTEMATIC DESIGN RELATED TO HIGHWAY SAFETY

A systematic highway design approach to meet driver needs is proposed. Consideration is given to the evolution of highway design, "objectifying" the design process, design consistency in relation to driver expectancy, and developing a cost-effectiveness methodology. Although publications of the American Assoc. of State Hwy. and Transportation Officials provide a unique framework for geometric design, they do not examine geometric design as a systematic process. A systems engineering design approach emphasizes the total design or task rather than the efficiency of component parts, and strives to maximize system performance at a given cost level or to minimize system cost at a given performance level. Objectifying the design process requires: a format for functionally classifying highways and a framework for defining highway design goals in each functional class; an objective description of driver, vehicle, traffic, and environmental characteristics; a definition of design speed as a function of design goals and constraints for each functional highway class; an objective delineation of design criteria; and synthesis. Synthesis of data on interactive relations must incorporate hazard measures, data matrixes, and statistical procedures. Six countermeasure approaches to driver guidance and control problems are to improve driver detection, increase driver perception and response time, eliminate "false cue" designs, decrease driver guidance and control demands, increase driver expectancy, and build "relief valve" designs. The decision process associated with cost-effectiveness assessment is detailed, and the need for sophisticated analysis and decisionmaking procedures is emphasized.

ANALYSIS OF THE PROBLEM OF URBAN UTILITY-POLE ACCIDENTS (ABRIDGMENT)

The problem of urban utility pole accidents was explored, using 1975 data on these accidents and other run-off-road accidents in 20 urban-suburban areas. It was established that utility poles were the most frequently struck and among the most aggressive roadside objects. When factors differentiating utility pole accidents from other single-vehicle accidents were examined, few differences were noted in variables describing the vehicle, the driver, or environmental conditions. Differences were detected in variables describing road characteristics, vehicle departure attitude, and characteristics of utility pole placement. It is clear from regression analysis that the overriding factor in predicting utility pole accidents is the number of poles. This variable not only identifies that a line of poles exists but also indicates average pole spacing since poles within 183 meters of either side of the struck pole were counted. If better measures of vehicle departure attitude were available (e.g. angle and speed), a higher proportion of variation in results might have been explained.

MATHEMATICAL MODELS THAT DESCRIBE LATERAL DISPLACEMENT PHENOMENA (ABRIDGMENT)

Data were collected to explain lateral displacement phenomena using two super 8-mm movie cameras to study the behavior of traffic in the right lane of freeways as it approaches a vehicle parked on the right shoulder. Vehicles of different sizes were placed on the right shoulder at varying distances from the freeway edge of the pavement. Two observers each operated a camera, one stationed on a crossover above the center of the freeway right lane and another stationed evenly with the parked vehicle on the other side of the freeway. Both films were later advanced simultaneously through stop-action projectors, and several parameters were extracted by visual counting or the construction of special scales placed on the screen to measure distance. Parameters included total volume of vehicles in the right lane including trucks and buses, distance between pavement edge and center of the traveling vehicle as it passed the parked vehicle, speed of individual vehicles in the right lane and adjacent lane, and headways in the right lane. Data were classified as geometric or traffic characteristics. Because each urban area had its own geometric and traffic characteristics, it appeared that general mathematical models are not feasible in analyzing lateral displacement.

EVALUATION OF PROGRAMS IN THE DEPARTMENT OF TRANSPORTATION--AN ASSESSMENT. REPORT TO THE CONGRESS OF THE UNITED STATES BY THE COMPTROLLER GENERAL

An assessment was made of the extent to which evaluation within the Dept. of Transportation (DOT) is an established part of the management process and the extent to which evaluation activities are aimed at serving congressional and executive branch decision-making needs. The following activities are recommended to the Secretary of Transportation: to continue DOT initiatives to develop a Departmental Program Monitoring and Evaluation System, including the formulation of DOT-wide guidelines for evaluation; to review specifications and measurements used in evaluating departmental program objectives, and to develop a means for clarifying objectives and measures with the appropriate congressional committees, the Office of Management and Budget, and agency officials; and to establish an evaluation planning process based on priority transportation objectives identified by DOT, the Congress, and others. Evaluation activities of the Office of the Secretary of Transportation, the Coast Guard, the Federal Aviation Administration, the Federal Hwy. Administration, the Federal Railroad Administration, the National Hwy. Traffic Safety Administration, and the Urban Mass Transportation Administration are separately discussed.

CONSOLIDATED TRANSPORTATION PROGRAM (1978-1982), MARYLAND

Forecasts are presented of Maryland Dept. of Transportation expenditures for operating, constructing, and improving transportation facilities during the period 1978-1982. Highway, transit, port, and aviation capital projects are included, as well as operating programs funded from the Department's Transportation Trust Fund. Complete operational and capital costs for transportation activities for FY 1978 are provided; those for FY 1979 through 1982 are shown for planning purposes only. The Consolidated Transportation Program (CTP) has been developed within the framework of the preliminary Maryland Transportation Plan and is consistent with the policies and the long-range plans described there. The program is based on schedule forecasts, revenue forecasts, and cost estimates which incorporate assumptions of future socioeconomic conditions and trends. The highway section of this CTP constitutes the annual update of the State Primary and Secondary Improvement Programs, which has heretofore been distributed as a separate document.

COLD-AIR PERFORMANCE OF FREE POWER TURBINE DESIGNED FOR 112-KILOWATT AUTOMOTIVE GAS-TURBINE ENGINE. 2. EFFECTS OF VARIABLE STATOR-VANE-CHORD SETTING ANGLE ON TURBINE PERFORMANCE. FINAL REPORT

The cold-air performance of the baseline power turbine designed for a 112-kilowatt automotive gas-turbine engine has been experimentally determined as part of the Dept. of Energy automotive gas-turbine program. Since this axial-flow power turbine has a variable stator for engine control and braking, performance data were taken at positive-power stator-vane-chord setting angles of 26 degrees, 30 degrees, 35 degrees (design), 40 degrees, and 50 degrees from the plane of rotation and at the nominal braking position of 107 degrees. The overall performance in terms of mass flow, torque, speed, and efficiency is presented, as well as overall diffuser performance and the results of rotor-exit radial surveys. Turbine efficiency increased to a maximum as the stator setting angle increased. For equivalent design speed and a design work factor of 1.172, the maximum total efficiency was 0.87 at the 45 degree setting angle although the total efficiency at the design setting angle of 35 degrees was 0.77. Turbine mass-flow and torque levels increased with increasing setting angle, with the maximum levels at the 50 degrees stator setting angle. At equivalent design speed and a design static-pressure ratio of 1.775, mass flow ranged from 48.5% to 133.5% of design and torque ranged from 33% to 142% of design as the stator was opened from the 26 degree to the 50 degree setting angle. The turbine braking power was determined at a nominal stator setting angle of 107 degrees. At equivalent design speed and static-pressure ratio, equivalent braking power was 10.8% of equivalent design power output. Turbine internal flow characteristics were determined from static-pressure measurements and rotor-exit radial surveys with probes. The rotor-hub reaction was negative for all conditions tested at stator setting angles below 40 degrees. Although the hub stage reaction was -0.160 at the 35 degrees setting angle (design), it was 0.131 at the 45 degrees setting angle (maximum efficiency). Overall diffuser total-pressure-loss coefficients that included both the diffuser and the exit collector were obtained over the range of diffuser-inlet critical velocity ratios tested. The loss coefficient varied from 0.2 to 0.4 as the inlet critical velocity ratio increased from 0.1 to 0.5.

THE SUSPA SOLID IMPACT SHOCK-ABSORBER, SYSTEM MENASCO (DER SUSPA-FESTSTOFF-AUFPRALLDAMPFER, SYSTEM MENASCO)

Solid-impact telescopic shock absorbers (silicone-elastomer) mounted horizontally with flanges or rubber-metal connections between a car's reinforced bumper and body have been proven in practice. Reaction forces absorb kinetic energy on impact. The bumper automatically returns to its original position and is ready to absorb impact again. Silicone-elastomer, used as filler for shock absorbers, has special requirements of low shear resistance and high compressibility. The material is liquid in its crude state and is precipitation-hardened using an integrated hardener at high temperature. Advantages of the shock absorber design are high efficiency due to an approximately 90% rectangular diagram, damping forces unaffected between -40 degrees and 70 degrees C, no damage to shock absorber for impact speeds up to 50 km/hr, and functional dimensions with large tolerance ranges that insure small production and performance tolerance ranges. Consideration is given to U.S. regulations requiring a bumper system on passenger vehicles that is capable of absorbing an impact velocity of up to 5 mph or 8 km/hr. The solid-impact shock absorber design is described in terms of static force variation, force variation versus impact stroke during collision, efficiency, temperature behavior, behavior at high and low speeds, long-term behavior, bending load tolerance, and fabrication scatterings. Drawings and diagrams are provided.

THE AUTOMOBILE AND THE ENVIRONMENT: AN INTERNATIONAL PERSPECTIVE

First versions of the six papers presented were written in 1972-1974 for the Environment Directorate of the Organisation for Economic Co-operation and Devel. Among the issues addressed are environmental implications of options in urban mobility, urban public transport, methods of traffic limitation in urban areas, implications of the automobile and the environment on the planning process, strategies for automobiles and cities in developing countries, and automotive air pollution and noise. The text of the papers was adjusted to read logically in 1977; some papers have been updated.

ENVIRONMENTAL IMPLICATIONS OF OPTIONS IN URBAN MOBILITY: OBSERVATIONS OF THE ENVIRONMENT COMMITTEE OF OECD [ORGANISATION FOR ECONOMIC CO-OPERATION AND DEVELOPMENT]

Besides pollution control, the rising demand for fuel is another critical problem brought on by the increasing numbers of motor vehicles in circulation. It is recommended that the available reserves be made to go further by reducing motor vehicle weight, adjusting engine design and maintenance, controlling traffic, and cutting back on power-consuming accessories (automatic transmission and air conditioning). Promotion of fuel-efficient automobiles through differential taxes and fuel taxes is also recommended. The relative economy of various forms of transportation should be examined: public transport, public automobile service, carpools, bicycles, and walking. New concepts in public transport service can be achieved by improved bus operations, innovative rail transit systems, car sharing, and selective limitations on private automobile use. Methods of improving bus service include priority at traffic lights, exclusive lanes, and tunnels. It has been found that construction of rapid rail transit without land use controls leads to added traffic congestion. A light railway or semi-metro system adapted from the tramway is considered preferable to conventional underground systems. Among ideas for public automobile service are bus pools (chartered bus service from a single suburban area), shared taxis, subscription carpools with special parking facilities, and "dial-a-ride" service. Among promising new techniques are Personal Rapid Transit (cabins on guideways) and "people movers." Plans to restrict the use of cars must be accompanied by a concurrent investment in public transport, in traffic diversion and management, and in pedestrian facilities. Land use control policies are needed to control the demand for transportation. For the future, it is believed that the automobile and public transport should complement each other within the goals set by city planners, backed by strong initiative and positive action by central governments, including experimentation and demonstration projects.

HS-026 708

URBAN PUBLIC TRANSPORT: SERVICE INNOVATIONS IN OPERATIONS, PLANNING AND TECHNOLOGY

The present state of development and planning is reported for a variety of recent urban transport initiatives in Western Europe, North America, and Japan. Outlined are the scope of future needs for public transport, the effects of mobility on the urban environment, the planning process, and the roles of government, particularly central government, in dealing with issues of urban mobility and urban environment. Innovations are possible in the incremental advance of existing transport techniques as well as in new technical capabilities. Institutional innovations are required (planning, administrative, and financial). The difficulties of providing improved transport service are centered not in technology but in gaps of communication and responsibility between institutions with transportation missions and those with other tasks (environmental quality, human factors application). Government action can improve urban public transport by overcoming these gaps which limit the understanding, the resources, or the responsibilities necessary to deal with urban transport policy. Among the specific topics discussed are new potentials in public transport service (horizontal elevators, Personal Rapid Transport); bus operations and the management of street and highway facilities (minibuses); tramways, rail rapid transit and suburban railroads; institutional innovations in planning and adminstration; automated guideway transit (small vehicle systems in localized or areawide service); and government and the pace and quality or urban transport evolution. Appended is a discussion of service characteristics of existing modes of urban transport.

HS-026 709

METHODS OF TRAFFIC LIMITATION IN URBAN AREAS

Methods are reviewed by which traffic volume is limited in every city worldwide, intentionally or unintentionally, by local or central government. Control may be exercised over particular classes of vehicles, in particular areas or streets, at particular times, or for particular purposes. The 35 control methods identified fall into three categories: traffic restriction, traffic restraint, and traffic avoidance. Traffic restriction methods include road closure, prohibitions (e.g. no turns), traffic management, vehicle regulation, and restriction of driver licenses. Traffic restraint methods include reducing traffic speed; designating lanes for buses, cycles or pedestrians; parking restrictions, controls and charges; and other methods of making private transport slower, more expensive, and less attractive. Traffic avoidance relies upon planning control of land use and transport infrastructure; methods include minimizing the need for travel by private motor vehicle, improvement of public transport, and restrictions on road building. It is concluded that effective methods are available to cities for selectively limiting traffic volume as the cities consider appropriate.

THE AUTOMOBILE AND THE ENVIRONMENT: IMPLICATIONS FOR THE PLANNING PROCESS

Changing awareness and attitudes concerning such social and environmental factors as air and water quality, noise, natural ecology, open space, and community structure are affecting the construction of transportation systems (new or larger airports, highways, bridges, and transit systems). Among the topics presented in an examination of the implications of this increased environmental awareness are an overall planning objective and strategy, institutional arrangements, decision-making responsibilities, community interaction, evaluation of alternatives, and the interrelation of system and project planning. Basic guidelines are presented for an integrated approach to incorporating social, economic, and environmental factors into transportation decision making. Key findings include the fact that the overall process is as important as the techniques employed; that social equity issues must be explicitly recognized and considered; and that different groups of people have different interests and priorities. It is proposed that all phases of a transportation planning and design process should have the following objectives: to clarify issues of choice; to fully inform decision makers; and to achieve substantial, effective community agreement on a feasible, equitable, and desirable course of action, including adequate compensation for groups who are adversely affected by the course of action. Increased consideration of environmental issues during system planning is recommended, as are individual project decisions formulated according to staged strategic commitments, in order to achieve flexibility to respond to changes in the overall plan.

AUTOMOBILES AND CITIES: STRATEGIES FOR DEVELOPING COUNTRIES

The impact of automobile ownership on major cities is explored, including cities in developing countries. Buses are considered the most effective immediate answer to the problem of traffic congestion; if the number of buses in cities of over a half million population were doubled and priority given to public transit on city streets, 135 million more rides per day could be provided at an investment of $4000 million, less than the cost of new roads or continuing congestion and less than 10% of the cost of equivalent subway capacity. Other alternatives suggested are group-riding taxis or public automobiles (1 taxi as substitute for 6 private cars). Physical constraints on private automobiles include auto-free zones, all-bus streets, and bans on curb parking; financial constraints on automobiles include charges for highway use and parking. Other causes of traffic congestion are the haphazard location and arrangement of urban activities, poor environment, and lack of physical relationship among housing, jobs, and services. Urban redevelopment is recommended that organizes and reduces travel requirements while improving the capacity of public transport. For new urban growth areas, community design and city planning are recommended. Transportation should not be used exclusively to support congestion but to avoid it and to help build satellite communities that are partially self-sufficient. Basic data on cities and motorization in developing countries are appended.

AUTOMOTIVE AIR POLLUTION AND NOISE: IMPLICATIONS FOR PUBLIC POLICY

Strategies are considered which enable countries to abate air pollution and noise from motor vehicles. Countries vary in climate and topography, extent of industrialization, and in levels of automobile ownership, but if present trends continue, all countries will be affected to some extent by air pollution and noise, particularly in urban areas. More accurate and more complete monitoring of air quality is needed to obtain information about the extent of the air pollution problem, as well as further research on the health effects of pollutants. Among the topics discussed are vehicle emission and noise standards, the need for uniform test procedures, the effects of major increases in the price of automobiles, effects of emission controls on driving performance and fuel economy, emission controls in the context of other vehicle modifications, controlling emissions from vehicles in use, dual standards for vehicle emission control (higher urban standards), limiting lead content in motor fuel, motor fuel quality, regulatory or economic controls, and controlling air quality and noise by reducing the use of cars. In the longer term, levels of automotive air pollution and noise could be lowered through rational urban and land use planning: shortened distances between home and work, school, and shops. Evolution in vehicle design due to advances in technology is also possible. Increased use of car-carrying trains and plane/rented car package trips could reduce long distance travel by automobile. The extent of future changes depends on the political climate within individual countries. Appended are a review of the literature on the health effects of lead from fuel, tables of national vehicle noise limits and of motor vehicle statistics, and discussions of the technology of vehicle emission and noise control.

HS-026 713

DRIVER BEHAVIOR EFFECTS ON FUEL CONSUMPTION IN URBAN DRIVING

A distinction is made between urban and freeway driving; fuel consumption at a given constant speed on the freeway is essentially independent of the driver. In two experimental studies, drivers were instructed to drive "other than normally with the traffic" to minimize either fuel consumption or trip time. For each 1% increase (decrease) in trip time compared to normal driving, fuel consumption increased (decreased) by about 1.1%. It was determined that expert drivers can save fuel without increasing trip time by skillfully adjusting their speed to avoid stops at traffic signals and that the formal problem involved in minimizing fuel consumption on an urban trip is so complicated that even a perfect fuel economy meter would not permit a driver to achieve this minimum. Three actions to reduce fuel consumption in urban traffic are suggested: anticipating conditions ahead so that braking is minimized; avoiding stopped delays; and using low acceleration levels. The possible effect of driver behavior on the overall traffic system is discussed.

ALCOHOL AND SPEED-ACCURACY TRADEOFF

Performance on two auditory choice reaction time (RT) tasks was studied in a group of 12 subjects under the influence of graded doses of ethyl alcohol ranging from placebo to 1 g/kg body weight. All subjects had normal hearing and color vision and were light to moderate social drinkers with no medical conditions that contraindicated alcohol consumption. They were instructed to abstain from alcohol and other drugs during the experiment and to fast at least four hours before sessions. The experiment consisted of six sessions on successive days, except for a 48-hour interval following the highest alcohol dose, and consisted of two independent tasks to measure subjects' ability to distinguish direction and pitch of aural stimuli. Deadline procedures were employed in side discrimination and pitch discrimination tasks to calculate the speed-accuracy tradeoff function (accuracy versus RT). The designated deadline was constant within 100 trial blocks. Before each block, the technician stated which deadline was operational. Subjects had to strive for 100% accuracy at the longest deadline, at least 90% accuracy at the middle deadline, and at least 70% accuracy at the shortest deadline. Accuracy declined as a function of alcohol dose, but alcohol did not significantly influence RT. Accuracy was not affected by task, although the pitch discrimination task required about 88 ms more time than the side discrimination task. Alcohol dose and task produced independent effects on the speed-accuracy tradeoff function. As dose increased, the slope of the tradeoff function declined; slopes were equivalent for the two tasks. The x-intercept, where accuracy equaled chance levels, was 90 ms greater for the pitch task than for the side task.

INFORMATION TRANSFER CHARACTERISTICS OF MOVING LIGHT SIGNALS [ON EMERGENCY VEHICLES]

Eight different configurations and color combinations of rotating beam emergency vehicle lights were evaluated in terms of information conveyed about rate and direction of travel when viewed at night. Lights were viewed moving toward or away from stationary observers at rates of 0, 5, and 10 meters per second for an overall range of 300-450 meters. Observers were 78 males between 19-26 years of age with substantial night driving experience. Each light signal was viewed by an independent nonoverlapping group of 9, 10, or 11 subjects. Each subject viewed 25 exposures of a single light, with five possible conditions (toward fast, toward slow, still, away slow, and away fast) occurring five times. Differences were found between individual lights with regard to motion illusions, signal-to-noise ratios, and overall error scores. Red lights conveyed more information than combinations of red and blue lenses in the same light. Twin lights were superior to single beacons, and twin models with a sequential mirror-generated flash pattern were superior to plain ones. Several lights created an illusion of receding motion when actually at rest. This was most severe for a side-to-side alternate flash pattern using red signals. Highly conspicuous lights were not necessarily those with the best information transfer characteristics. Cues relevant to the perceptual task of the study appeared to be provided by changes in light intensity with distance rather than by changes in angular displacement.

THE ANTHROPOMETRY OF UNITED STATES ARMY MEN AND WOMEN: 1946-1977

Information on the body size of Army personnel, including men and women, has been collected during several anthropometric surveys conducted between 1946-1977. The widespread belief that height and weight of the general population are increasing is not supported by data for Army men and women. Although increases have been found in some body measurements of Army personnel, these changes are slight. Contrasts in body size and proportions between Army men and women are significant in terms of clothing design and the human engineering of equipment and material for use by both men and women. These differences concern sitting and eye heights, shoulder and hip breadths, and arm and leg functional reaches. Survey data are discussed and tabulated.

IMPACT OF HIGHWAY METRICATION ON TRAFFIC ACCIDENTS AND LONG-TERM TRENDS IN VEHICLE SPEEDS FOR ROADS WITH RESULTANT INCREASED SPEED LIMITS

The impact of metrication of roadside speed signs upon vehicle speeds was investigated for four different road types using concealed roadside radar. The study was conducted one year after metrication to determine whether there were any long-term changes in traffic patterns in addition to the short-term influences reported previously. There was no evidence of any tendency for drivers to increase traveled speed, even on the two roads for which metrication resulted in an increase in the speed limit. Analysis of accident statistics for the month following metrication revealed no significant increase in accident rate over that projected from a nine-year record of accident trends. This reflects similar experiences in Australia and India following metrication. It is concluded that highway metrication does not present the safety hazard suggested by critics of the program.

THE DEVELOPMENT OF A MICROWAVE RADIOMETER FOR USE AS A HIGHWAY ICE DETECTOR. FINAL REPORT

A program was designed to develop a system capable of detecting snow, ice, frost, or slush over a highway bridge deck area greater than 4 x 2 feet (1.2 x 0.6 m) and generate a valid alarm signal to warn motorists of a hazard. The detection system selected was a microwave radiometer operating at 10 GHz which continously samples a reference noise source and internal amplifier noise to provide measurement corrections of radiated power received from the road surface being observed. The principal radiometer components are a rectangular horn antenna, a sensitive receiver, and a signal processor/alarm unit. The successive program phases were: design optimization and system tradeoffs; breadboard model laboratory and field tests; and prototype model design, fabrication and test. Test results on asphalt and concrete roadway simulators, as well as actual asphalt roads, correlated with previously published radiometric temperatures for similar surfaces. The following road conditions were detectable: dry/warm; dry/cold; wet; slush; ice layer (0.1 cm. minimum); and snow layer (1 cm. minimum). All road hazard detection objectives were met except for frost detection. Descriptions of recommended additional effort are presented, including detailed evaluation of the prototype model; advanced alarm logic; self-test techniques; and a scanning antenna to cover increased road areas.

DUAL PHASE STEEL PRODUCTION BUMPERS

The use of high strength , low-alloy (HSLA) dual phase steel is an effective method of reducing bumper weight while meeting ever-increasing government performance requirements. A paper analysis, followed by a hardware evaluation, successfully substituted "dual phase" for conventional HSLA steel at a reduced thickness. This steel, basically an annealed vanadium strengthened SAE 980 steel, has a tensile strength of 90 ksi minimum and an elongation of 27% minimum. Bumpers for the all-new 1979 Cadillac Eldorado were designed and released using dual phase steel with yield strengths of 70-80 ksi for the face bars. Production problems were overcome by modifications of mechanical properties and increased development experience with this steel. To achieve the full work-hardening potential of dual phase steel, bumper sections and draw dies must be designed for a uniform strain greater than 3%. Future dual phase steel for bumpers in the 80-120 ksi range is desirable, but further improvements in steel-making technology and part and die design techniques are required to achieve this goal.

EVALUATION OF LUBRICANTS FOR JAPANESE SMALL AIR-COOLED TWO-CYCLE ENGINES

Test methods are described for evaluation of lubricants for small air-cooled two-cycle engines used in Japan, and some results are presented. The effect of base oil composition and additive type on lubricant performance is also described. The following conclusions were drawn: composition of base stocks affects piston cleanliness, exhaust port blocking and smoke; polybutene reduces exhaust smoke, but accelerates the formation of tacky film on the piston surfaces. Selected combinations of metallic sulfonate and metallic phenate additives can give good piston cleanliness, further improved by supplementary addition of ashless dispersants. Ashless dispersant, by itself, gives reduction of combustion chamber deposits and of plug fouling, but cannot alone provide satisfactory piston cleanliness and ring stick prevention in air cooled engines. Less than 0.25% of ash content in two-cycle engine oil is desirable for prevention of spark plug fouling and combustion chamber deposits. Overbased detergents, despite low ash concentration, could raise the incidence of plug fouling. Barium type additives act as deposit softeners and reduce piston rings sticking, exhaust port blocking, and combustion chamber deposits.

PERFORMANCE TEST METHODS FOR TWO-STROKE CYCLE ENGINE LUBRICANTS INCLUDING LEAN FUEL-OIL RATIO CONDITIONS

The development of 2-stroke cycle gasoline engines with higher specific outputs and improved environmental aspects has resulted in more stringent lubricating oil requirements. A classification system is being generated by SAE/ASTM/API in cooperation with the Coordinating European Council (CEC) to facilitate selection of suitable oils with different performance levels for various applications. Standardized CEC Test Methods and European in-house tests used for 2-stroke oil development are described and discussed; typical bench and field test results are presented, obtained both with reference oils and with proprietary formulations incorporating modern concepts of base oil and additive technology. Biodegradeable lubricants and special oils for use at lean fuel/oil ratios have been developed. It is concluded that a multi-purpose oil giving optimum performance in all types of 2-stroke engines and under all practical operating conditions is not in sight; it will be difficult to fit marketed oils covering a wide performance spectrum into the proposed API/CEC classification system based on three grades. The 2-stroke engine should nevertheless continue to be valuable as a power unit for a large variety of machines and equipment. Photographs, diagrams and charts are included.

HS-026 722

FUTURE TWO-CYCLE ENGINE OIL DEVELOPMENT--A NEW CHALLENGE

Since today's two-cycle engine oils are not expected to meet future engine oil requirements adequately, it is recommended that oil developers use a Comprehensive Oil Development Plan for future oils. The plan should include five key elements: engine manufacturer contact, mechanism studies and failure analysis, oil formulating, laboratory engine evaluation, and field evaluation. These elements are described through examples of lubrication and deposit programs. The most important future oil performance requirement is considered to be scuffing control. Data from the G15 laboratory engine scuff test are presented, which should assist in the development of future oils. The importance of mechanism studies and failure analysis programs to support formulation for antiscuffing is stressed. A review of published air-cooled engine deposit test procedures has shown the lack of world-wide standardization. Satisfactory water-cooled engine test procedures are available, although the standardized BIA-TCW test needs modernization to increase test severity and the ability to separate oils of different quality. Studies of laboratory engine test procedures show a need for better correlation with field evaluations.

EMISSION FACILITY DESIGN CRITERIA

A detailed review is presented of the layout and design criteria of the new Oldsmobile emission test facility. This facility represents Oldsmobile's response to the need for new accurate, reliable and versatile emission test facility to accommodate the more stringent Federal and State emission standards. The facility consists of three operational test sites, with capability of future expansion to five, and can test either gasoline or diesel vehicles. Sites provide a dynamometer for preparing cars and two evaporative emission S.H.E.D.'s; precise control of building temperature, humidity and background air quality; and latest state-of-the-art instrumentation for measuring hydrocarbons, carbon-monoxide, carbon dioxide, oxides of nitrogen, oxygen, continuous air/fuel ratio, methane, evaporative emissions, fuel economy, and diesel particulates. Its measurement capabilities, computer data handling, and storage and retrieval processes are discussed, as is a special data reduction program capable of producing two or three dimensional plots of dynamic engine emission parameters. The final section reviews the facility's physical design, data acquisition capability, and computer versatility, permitting updating to accommodate changes in the fast-moving field of emission measurement technology.

RELATION BETWEEN ROADSIDE SIGNS AND TRAFFIC ACCIDENTS: FIELD INVESTIGATION

The relation between roadside signs located nearest to urban traffic intersections and traffic accidents was systematically investigated. Specific sign elements studied were total number, type (public vs. private), size, and color. The dependent variable was the number of accidents during 1975 at 60 intersection approaches where the driver who entered the intersection from the direction selected was found to be at fault in the police accident investigation report. The intersections were selected randomly from cross intersections in Austin where at least one accident occurred in 1975. Results indicate that a number of sign elements had a significant relation to accidents at intersections controlled by traffic signals. A wider range of engineering alternatives is needed at some stop-sign intersections to counteract the effects of potential distractors, such as design of a larger or brighter target traffic device or employment of neutral background shields to contrast the target and its surroundings. When such alternatives are not feasible at sites with many distractors, traffic signals should be used instead of stop signs.

ADVANCE ROAD SIGN MESSAGES FOR HIGHWAY ADVISORY RADIO SYSTEMS (ABRIDGMENT)

Two laboratory studies were conducted to evaluate candidate messages for display on an advance-notice road sign, directing drivers to tune in their radios for reception of traffic information. Study 1 investigated the effect of ten candidate messages on 247 subjects in independent groups of about 25 subjects each, using a questionnaire. In Study 2, 40 subjects were asked to select one of a pair of messages that better prepared them to receive the radio message. It was found that when the objective is to imply an urgency to tune to a radio frequency, the word "alert" is most effective; all data suggest that it implies a non-routine, incident-related situation requiring action. Though the word "radio" is implied from the advisory, preference data support its inclusion. Omission of the word "traffic" can result in misunderstanding the message RADIO ALERT. Based on the two studies, RADIO TRAFFIC ALERT is recommended, as well as the statement "TURN TO (frequency number)" or "TUNE DIAL TO (frequency number)." The single word "tune" is well understood. Some uncertainty existed among the subjects as to whether the radio dial number shown was AM or FM.

LEGIBILITY STUDY OF A LAMP MATRIX SIGN (ABRIDGMENT)

A field study was made of the legibility of a lamp matrix sign, which generated 46-cm (18-in) characters, to determine legibility distance as well as other display characteristics. The maximum distance was determined at which each of 20 subjects could read three test words. The mean legibility distance for all subjects was about 255 m (840 ft), translating to 5.58 m/cm (46.7 ft/in) of letter height. The 85th percentile legibility distance of a 46-cm matrix sign is about 4.2 m/cm of letter height. The closeness of the corrected static visual acuities of the subject population and the national population and the general agreement between the study mean and previously reported averages further substantiates the results. As the study was limited to only one size of lamp matrix display, generalizations could not be made about other sizes or types of display. Mention is also made of previous field experience showing that the brightness of the lamps used has a considerable effect on legibility.

REAL-TIME DIVERSION OF FREEWAY TRAFFIC DURING MAINTENANCE OPERATIONS (ABRIDGMENT)

A changeable message signing system for use in diverting vehicles around an incident on a freeway and redistributing traffic on alternate routes was tested and the results analyzed. Freeway maintenance both under management (informational and advisory signs) and nonmanagement (no sign) operations was analyzed on a case study basis. Phase 1 of the studies involved routing traffic along the service road, using matrix signs; phase 2 would route traffic to alternate arterial roads when continuous service roads were not available, using matrix and trailblazer signs, but no incidents of sufficient duration occurred in locations to warrant this procedure. Questionnaires were distributed for evaluation of the information displayed and suggestions for further information. Results showed that in all cases, exit ramp volumes increased for signed (managed) incidents compared to nonsigned (nonmanaged) natural diversion conditions. For informational signs only, increases ranged from 125.9% to 324.7% for the four case studies; when diversion messages were presented, increases ranged from 147.3% to 343.8%. A preference was indicated by motorists for diversionary information. In one case, motorists reentered the freeway before they had cleared the blockage, indicating a need for a supplemental sign or advisory to tell drivers when to reenter the freeway.

PEDESTRIAN MOVEMENT AT THE 1980 WINTER OLYMPICS SKI JUMP

Options are described and evaluated for the location of bus staging areas and the movement of pedestrians between these areas and the Intervale ski jump site at the 1980 Winter Olympic Games at Lake Placid, N.Y. These options are analyzed in terms of impacts on the environment, spectators walking under winter conditions, traffic flow and accidents, cost, maintenance, and post-Olympic implementation considerations. A comparative analysis is made of these impacts on each of four options for pedestrian flow. Results show that either a pedestrian bridge or a signalized crosswalk across the main route appear superior, minimizing pedestrian-vehicle conflicts, separating spectators from dignitaries and officials, and consolidating bus staging activities in a single adequately sized location. Options that assume joint use of the road by vehicles and pedestrians should be avoided because of the crucial requirement for maximum road capacity to handle bus circulation. Further factors to be considered include lighting, liability, environmental constraints, land availability, and budgetary limitations.

CREATION OF PEDESTRIAN STREETS IN CITY CENTERS (ABRIDGMENT)

Since 1970, a number of Tokyo streets have been opened to pedestrians, sometimes with a ban on vehicle traffic for only a certain period of the day; the procedure is now widespread in Japan. Increasing the number of these streets has caused a decrease in deaths and injuries from traffic accidents. Methods of conversion include the periodic traffic ban on heavily travelled streets, and construction of underground shopping centers and arcade shopping streets. Careful planning of alternative routes is essential. The concept of traffic cells as used in the Federal Republic of Germany is described, and the establishment of a similar arrangement in Nagano City Center is projected. Completion of the Nagano project is planned for 1985.

TREATMENTS OF OVERPASSES AND UNDERCROSSINGS FOR THE DISABLED: EARLY REPORT ON THE STATE OF THE ART (ABRIDGMENT)

An evaluation is made of the state-of-the-art for crossing treatments for the disabled. The study approach used a team leader and a panel of disabled persons who visited crossing facilities representative of current treatments. The results of visits to three overpasses in the San Francisco Bay Area indicated the following major deficiencies. At a pedestrian-motor vehicle overpass there were: no curb cuts at one end, presenting a problem for the wheel-chair bound; no crosswalks or pedestrian warning signs to motorists; obstructed sight lines at areas where high speed on- and off-ramps crossed the pedestrian pathway; no railing to protect pedestrians from long drop-offs on the approaches; greater than acceptable cross slopes on structure sidewalks; no level areas on either side of the freeway motor vehicle on- and off-ramps. At a pedestrian overpass accessible by two solid-core concrete spiral ramps, the following deficiencies were noted: level resting areas are needed; the railing was difficult to grasp; the solid concrete core made it impossible to see or be seen by persons travelling in opposite directions on the spiral; wheelchairs drifted to the outside of the ramp. The third overpass was more acceptable, the only major problem being maze-like barriers at the bottom of each ramp to discourage speeding bicyclists and skateboarders; this caused great difficulty for wheelchair and walker users and for the blind. Plastic screening attached to sections of the fence to protect the privacy of nearby residences reduced noise levels from the freeway below and made it easier for the blind to detect direction and potential conflicts. Since the disabled are a heterogeneous group with varied mobility limitations and needs, it was concluded that a combination of treatments is needed. Motor vehicle-pedestrian overpasses with high-speed ramps are hostile environments where additions of curb cuts may not be adequate. Spiral ramps may be useful but careful design is necessary. Using disabled panelists is a useful technique for evaluating crossing arrangements.

MODEL PEDESTRIAN SAFETY PROGRAM: AN OVERVIEW

The model pedestrian safety program was the final project in a series of pedestrian studies. The program was designed to consolidate the results of the earlier studies with pedestrian safety data from numerous other sources into a usable format and to develop guidelines for communities interested in initiating or augmenting a pedestrian safety program. An overview of the entire project is presented. A literature review classified 450 documents into a 71-item subject matrix for easy reference. During the review of operational experience, contacts were made with 19 American communities to gather data on the day-to-day operations of ongoing pedestrian safety efforts, and a six-point users' manual was developed. These guidelines detail identification of the extent of the pedestrian safety problem and of alternative countermeasure solutions, selection of the best alternative implementation of the alternative chosen, evaluation of its effectiveness once initiated, and maintenance of the safety program.

SOME CHARACTERISTICS OF BICYCLE TRAVEL AND ACCIDENTS IN TOWNS [IN ISRAEL]

Findings of bicycle field surveys are presented, including 685 interviews with riders in six Israeli towns having very different levels of bicycle use. Data are analyzed on bicycle accidents and on mode of travel to work and school in 29 towns. Estimates are made of the number of bicycles in use, the number of riders, and annual travel by age and sex of rider for major trip purposes. It is concluded that bicycle travel represents an overall addition of 12% to urban travel at present levels of use in Israel and, on this basis, accident risk per kilometer of bicycle travel is about the same or even lower than that for passenger automobiles. Bicycles are not only an extremely important means of transport for the 10- to 19-year age group, but in towns where bicycle use is high (20% of total trips) all ages of males and females use them actively for shopping, recreation, and work. Trip lengths are rarely above 5 km and vary according to age, sex and trip purpose; trip length characteristics are usually similar to those found in Europe. For towns with flat topography and populations of 100,000 or less, multiple regression analysis indicated that six factors accounted for 59% of the variance in bicycle use in the 24 towns studied: population, radius, density, number of persons per household, percent welfare expenditure, and percent working out of town. In very small and poor towns, walking was found to be an alternative to bicycling; in other towns, industry-provided transportation seemed to be an alternative mode. For towns in developing countries, trying to keep transport costs low, and for protection of environmental quality, at least some parts of the urban structure should be planned to accommodate and encourage bicycle travel.

CYCLIST BEHAVIOR AT SIGNALIZED INTERSECTIONS

A study was made of cyclist behavior patterns at signalized intersections, to determine which types of bicycle traffic regulators are most likely to reduce bicycle/motor vehicle conflicts. Cyclist behavior was recorded during Feb. 1977 in Tempe, Ariz., at nine intersections, selected for their various bicycle facilities. At three approaches classified according to the type of push-button traffic signal available and the existence of a bike lane, the rate of use of the three types of push buttons--standard, cyclist, and cyclist-pedestrian--are compared. The effect on push button use of the presence of motor vehicles is analyzed by the type of intersection. Cyclist queuing patterns at the intersections, the use of pedestrian crosswalks by cyclists, and cyclist delay caused by vehicles turning right at the intersection were also studied. Cyclist push buttons are used most frequently and induce the majority of cyclists to stop in the most suitable queue area; cyclist-pedestrian and standard push-buttons cause more cyclists to stop in the zone with the greatest potential of accident occurrence. Painted bike lanes have no effect on the rate of use of push buttons or on the safety queue area. Cyclists are willing to use the crosswalk if it is not too far from their route of travel. To achieve maximum use, future installations of push buttons should be cyclist push buttons, and if possible, other types should be replaced with this type. Bicycle traffic at intersections should be channeled by providing cyclists with bicycle crossings or painted queue areas to avoid motor vehicle-bicycle conflicts. Cyclists should be encouraged to follow the pedestrian walking signals, either by stating this as a rule or by posting signs.

EVALUATION BY EXPERIENCED RIDERS OF A NEW BICYCLE LANE IN AN ESTABLISHED BIKEWAY SYSTEM

The attitudes of cyclists toward a newly established on-street bicycle lane and its effect on their route selection were analyzed by pre- and post-bicycle lane traffic counts. Cyclists rated the street as a much improved bicycle route, and both the mapping interview studies and the traffic counts showed that many cyclists shifted their route selection to take advantage of the bicycle lanes. These ratings and route selection shifts occurred because cyclists believed the lanes made riding safer and more convenient by giving cyclists their own area on the street. Bicycle lane approval and usage were strongly related to the age of the cyclist; those 25 and older perceived the greatest degree of improvement and were most strongly influenced in route selection. College age (18 to 24) cyclists perceived the smallest degree of improvement and were least influenced in route selection by the new lanes. A following discussion by John Forester opposed the thesis that bike lanes are safer, citing evidence that painting the normal bike-lane stripe modifies neither cyclists' nor motorists' behavior, and disputed the definition of "experienced cyclists" and the assessment of the hazards of local roadways. In rebuttal, the original authors questioned the relevance of this criticism. and urged a cycling policy to appeal to a broad section of the population.

NORTH CAROLINA'S BICYCLING HIGHWAYS

The bicycle program of the North Carolina Dept. of Transportation has initiated a unique project called "bicycling highways" to develop a statewide bicycle route system on existing roads of the state's primary and secondary highway systems. Although no roadway where automobiles and bicycles mix can ever be totally safe, many highways, unknown to the majority of people, are relatively safe for bicycling, due to their low traffic volume and good roadway conditions. By linking these roads throughout the state and providing detailed route information, a safer environment for the growing bicycle population is expected. The methodology is described that was undertaken in the selection of highways, as are survey techniques, information gathering procedures, map drafting, and reproduction of copies of the finished product. The resulting maps and narrative provide a very usable and informative product, requiring only small amounts of money and resources.

COMPARISON OF CALIFORNIA ACCIDENT RATES FOR SINGLE AND DOUBLE TRACTOR-TRAILER COMBINATION TRUCKS. FINAL REPORT

The relative safety of two types of truck combination vehicles, single (a tractor unit attached to a semitrailer) and double (tractor-semitrailer-full trailer,), are compared. California was identified as the state having the closest to a 50-50 split between the two truck classifications, and 1974 data represents the most recent year for which both detailed California accident and exposure data existed. The 1974 accident data were combined with estimates of truck exposure to arrive at accident and injury rates based on vehicle miles of travel. Average cargo weights were estimated in order to evaluate the safety of the two vehicle types on the basis of cargo ton-miles of travel. There was no significant difference between the number of accidents or injuries per million vehicle miles (MVM) of travel for the two vehicles. Doubles accidents resulted in a significantly higher number of fatalities per MVM. Based on the cargo hauled, singles had a significantly higher accident frequency and injury rate per million cargo ton-miles of travel, but there was no difference in the number of fatalities.

TRANSPORTATION AND THE FUTURE

An introductory overview is presented of currently emerging and future technological developments in U.S. transportation. The characteristics of future transportation systems will be determined largely by their missions and by the character of their environment. Demographic shifts place added emphasis on automated systems because of a decreasing labor pool of young and middle-aged Americans, and on systems to serve low-density, suburban, and rural areas. Energy constraints may make electrically-powered systems more attractive. Future urban transportation systems will probably consist of a combination of options, including technologically upgraded versions of existing options, as well as new options, such as personal rapid transit or dual mode. Bus systems to serve rural or exurban areas are also developing, and may be tied into evolving urban systems. The passenger car, or a similar option, will probably retain dominance in the transportation scene. Design changes have already made cars more fuel-efficent, and new engine technologies also appear promising in the longer term (post-1985). Energy shortages may necessitate more reliance on intercity rail systems, with buses serving lower density routes. After the turn of the century, tracked levitated vehicles may supplant high-speed trains on high-density routes. Energy-efficient jet transports and new short-range, short-takeoff aircraft should enter service in the 1980's. Supersonic, hypersonic, and lighter-than-air aircraft may also have long-term applicability. Trucks are growing larger and are consuming less fuel on a relative ton-mile basis. Containerization and automated freight handling should improve their compatibility with rail and air freight systems. Nuclear power freighters and tankers may appear on sea routes, with inland vessels or barges carried as intermodal containers. New pipeline technologies are also emerging. The space shuttle will enter service in the early 1980's.

CALIFORNIA TRAFFIC SAFETY EDUCATION TASK FORCE REPORT

A two-year study is described which resulted in the development of a comprehensive traffic safety education plan. This plan will be used as a guide by the California Dept. of Education to establish a statewide traffic safety education program. The study involved gathering, reviewing, and evaluating data and materials on all elements of traffic safety education. The plan identifies critical and priority problems and provides recommendations for their solutions as well as for immediate and long-range program implementations, program phases, time frames, and estimated costs. Subject areas addressed include alcohol and drug safety education, bicycle safety education, driver education, driver improvement, manpower development, motorcycle safety education, passenger safety education and pedestrian education.

BASELINE TESTS OF THE ELECTRA-VAN MULTIPURPOSE ELECTRIC VAN

The Electra-Van, Model 500-108, an electric, quarter-ton, multipurpose van, was tested at the Army Proving Ground Test Facilities in Aberdeen, Md., as part of a Dept. of Energy project to characterize the state of the art of electric vehicles. The Electra-Van, manufactured by Jet Industries, Inc. (Austin, Tex.), is a converted Subaru minivan powered by 18 6-volt batteries connected to the motor through a semiconductor controlled rectifier controller. The controller is actuated by a foot pedal to control motor speed. The 14.2 hp motor drives the rear wheel through a four-speed manual transmission. No regenerative braking is provided. The Electra-Van underwent range tests at constant speed and under driving schedules, and acceleration and coastdown tests. The vehicle, instrumentation, and test procedures are described. Test results are presented and discussed concerning maximum speed, maximum acceleration, gradeability, road-energy consumption, road-power requirements, and indicated energy consumption. Battery performance data are provided, as well as braking test results and driver reaction. Appended are a vehicle summary data sheet, a description of the vehicle test track, and vehicle preparation and test procedure descriptions.

ANTHROPOMETRIC SOURCE BOOK. VOL. 1: ANTHROPOMETRY FOR DESIGNERS

A large mass of anthropometric data are assembled which define the physical size, mass distribution properties, and dynamic capabilities of U.S. and selected foreign adult poplations. Aimed specifically to meet the needs of design engineers engaged in the design and execution of clothing, equipment, and workspaces for the NASA Space Shuttle Program, the book is also designed to be of use to human engineers in a wide variety of fields. It is not only a comprehensive source of specific anthropometric information but also a guide to the effective applications of such data. Subjects covered include physical changes in the zero-g environment, variability in body size, mass distribution properties of the human body, arm and leg reach, joint motion, strength, sizing and design of clothing and workspaces, and statistical guidelines. Material presented includes such unpublished anthropometric data measured under one-g and zero-g conditions. Also included are 1985 body size projections and design of cutouts of quarter-scale two-dimensional manikins for use by designers.

THE AFTERMATH: AIR BAGS AND US. ROAD AND TRACK READERS RESPOND TO THE PASSIVE RESTRAINT CONTROVERSY

Controversy over passive restraint devices in automobiles was examined in a survey of Road and Track magazine readers. A total of 38,449 questionnaires provided data on frequency of safety belt use, preferred type of safety device (conventional lap/shoulder restraints, passive safety belts as in the Volkswagen Rabbit, or air bags), whether air bags should be optional for persons who want them, and whether Congress should repeal air bag legislation. Cars from 1970-1979 model years were evaluated. The estimate that 71% wore belts all the time was about 3.5 times higher than the figure from National Hwy. Traffic Safety Administration studies and about double that in a study of stopped cars involved in accidents. Reasons for wearing safety belts only part of the time or never included the usual excuses: individuals did not feel the need to wear belts below a speed of 40 mph, did not take the time to fasten belts, and only drove short distances. Several readers complained about shoulder belts applying too much pressure on their breasts or straps chafing their necks. Others commented that belts were inconvenient to put on and were restrictive and that automatic locking devices tightened belts when cars were driven on rough roads. Most respondents for all model year cars preferred conventional safety belts, indicated air bags should be optional for persons who want them, and stated that Congress should repeal air bag legislation. Sample responses are included.

ROADSIDE SAFETY APPURTENANCES

This compilation of 12 papers focuses on highway safety devices. Specific topics of interest are a cost-effectiveness model for guard rail selection, computerized inventory and priority analysis for roadside obstacles, test vehicle kinematics by high-speed photography and accelerometer data, experimental evaluation of a portable energy-absorbing system for highway service vehicles, crash test performance of a guard rail median barrier and temporary construction zone crash cushion, properties of guard rail posts for various soil types, development and testing of a breakaway support coupling for light poles, dynamic testing of malleable aluminum transformer bases for highway luminaires, pendulum tests of breakaway wood sign supports using crushable bumpers, breakaway sign testing, and evaluation of bolted-base steel channel sign posts.

PERFORMANCE OF HIGHWAY SAFETY DEVICES

Accident records were compiled over a 5-year period (1971-1975) to evaluate the performance of roadside barriers, impact attenuators, slip base sign supports, and frangible base luminaire supports on highways in New York State. Data were collected on guide rails and median barriers, sign and luminaire supports, and impact attenuators (sand-filled plastic barrels, empty steel drums, and water-filled vinyl tubes). Design and construction variables incorporated in the analysis were barrier or impact attenuator type, impact location on barrier, impact conditions, vehicle size, and barrier mounting height. Parameters used to evaluate the performance of safety appurtenances included injury severity, vehicle reaction, and maintenance requirements. In total, 392 impacts on guide rails and median barriers were recorded during the study period, with 90% occurring during 1972 and 1973. All attenuators performed well in preventing serious injuries to occupants of impacting vehicles. Barrier penetration occurred in only 4% of mid-section accidents. Based on 10 accidents, slip base sign supports appeared to perform satisfactorily. Based on 78 accidents, the performance of aluminum frangible-base luminaire supports was excellent. Most serious accidents related to specific problems with individual attenuators or with secondary collisions. Although large differences in maintenance costs were apparent among highway safety devices, total cost depended on device installation cost and on the number of impacts a device could withstand before replacement was required.

COST-EFFECTIVENESS MODEL FOR GUARDRAIL SELECTION (ABRIDGEMENT)

This program was designed to develop a cost-effectiveness model for guardrail selection that would include cost parameters for various guardrail configurations and criteria for the analysis of system effectiveness under dynamic impact conditions. Eleven guardrail types were chosen for inclusion in the program. Impact category values concerned vehicle size, vehicle speed, and angle of impact. A present worth probabilistic formulation was employed in developing the cost/effectiveness model, combining guardrail installation cost and annual maintenance and accident costs into a single equivalent sum at zero time. Of alternatives compared, the one with the lowest present worth was the most economical. To apply the model formulation in developing a computer algorithm, it was necessary to estimate traffic mix, number of encroachments, probability of out-of-control vehicles traversing offset distance to the guardrail or obstacle, distribution of vehicle speeds, impact angles, accident severity, travel delay time for accident blockage and guardrail repair, costs associated with injury and property damage (vehicles and guardrail), and service life of guardrail and rate of interest. Cost-effectiveness values encompassed government costs, societal costs, total costs (government and societal costs), benefits, and a benefit-to-cost ratio. A COCOST program for comparative cost-effectiveness values and ranking of guardrail types, with given roadway conditions, was developed. The COCOST users manual covers basic operations and limitations of the program and includes computer program descriptions and listings, site selection tables based on representative costs and input values, and sample problems for applying the computer program. A sample COCOST output sheet is illustrated.

COMPUTERIZED INVENTORY AND PRIORITY ANALYSIS FOR ROADSIDE OBSTACLES (ABRIDGMENT)

A computerized inventory and priority ranking scheme for roadside obstacles is described. Highway safety is significantly influenced by design and maintenance of the roadside environment. In 1976, over 26% of all fatal accidents in Michigan involved collisions with fixed objects in or adjacent to the roadway. To provide material for a computerized information system based on an inventory of all roadside obstacles in the city of Livonia, Mich., data on roadside obstacles were gathered using 35-mm color photologs and the following factors extracted: object type, lateral distance of object from edge of the roadway, physical dimensions of object, and existence of curbs along the roadway. Obstacle type and rigidity were reflected in a severity ranking index assigned to 12 categories of roadside obstacles. It was determined that roadside obstacles presenting the greatest hazard potential (trees, utility poles, mast arm supports, buildings, and guard rails) constitute 48% of all roadside obstacles recorded in the inventory. The inventory system incorporates a prioritization mechanism that provides traffic engineers with a measure of the relative hazard potential of each obstacle type and with information on the priority to be given to eliminating or protecting that obstacle. Planned improvement of high-severity potential obstacles may be a cost-effective way to reduce accidents and/or accident severity.

TEST VEHICLE KINEMATICS BY HIGH-SPEED PHOTOGRAPHY AND ACCELEROMETER DATA (ABRIDGMENT)

Experimental test data show how data acquisition techniques of high-speed photography and accelerometer readings compare with theoretical values in the evaluation of vehicle kinematics relative to guardrail and median barrier systems. Although it was assumed that differentiation of photographic data would be less accurate than integration of accelerometer data for desired kinematic quantities, it was found that cine data yield as accurate and probably more accurate results than accelerometer data. Considerably more instrumentation is necessary for the retrieval of accelerometer data; initial conditions must be known in the integration process, and instantaneous direction must be determined if motion is curvilinear. High-speed cine retrieval has the advantages of greater simplicity and the self-starting characteristic, but care must be exercised in data differentiation.

Errors caused by differentiation of curve fits near ends of sampled data can be made less significant if the period of interest is bracketed on both ends by data sampling.

EXPERIMENTAL EVALUATION OF A PORTABLE ENERGY-ABSORBING SYSTEM FOR HIGHWAY SERVICE VEHICLES (ABRIDGMENT)

A portable energy-absorbing system attached to the rear of a highway service vehicle was subjected to crash testing in a study to design a system for protecting the motoring public and service personnel engaged in highway maintenance operations. The system was developed to absorb most energy dissipated in high-speed collisions between automobiles and highway service vehicles in such a way that acceleration and acceleration rates of vehicles are within guidelines specified by the Federal Hwy. Administration. System components include a service vehicle guidance frame, energy-absorbing pipes, and an impacting plate assembly. Four full-scale crash tests were conducted to evaluate system performance with respect to structural adequacy, impact severity, and vehicle trajectory. Testing with four vehicles (Ford Maverick, Pontiac, and two Plymouths) demonstrated effective system performance in the areas of energy dissipation, cost, eccentric impact, damage, and design.

CRASH TEST PERFORMANCE OF A GUARDRAIL MEDIAN BARRIER AND TEMPORARY CONSTRUCTION-ZONE CRASH CUSHION (ABRIDGMENT)

The Guard Rail Energy Absorbing Terminal (G-R-E-A-T) and the G-R-E-A-T Construction Zone, restorable attenuator systems developed to cushion narrow stationary and construction zone hazards, are examined. The G-R-E-A-T crash cushion consists of crushable Hi-Dri cartridges surrounded by steel thrie-beam guard rail. When hit head on, thrie-beam fender panels telescope backward and permit impact energy to be dissipated in crushing lightweight concrete Hi-Dri cells. When impacted on the side, side panels redirect the errant vehicle away at a shallow exit angle. Hi-Dri cartridges contain many cylindrical cells made of lightweight concrete which are bonded to plywood retainer panels and encased in a moisture-resistant box. Deflector panels are attached to the back of each fender panel when the G-R-E-A-T is used in median barrier applications where traffic is going the wrong way on the left side of the unit. Tests were conducted with drivers of four vehicles (heavy car centered on unit nose, light car centered on unit nose, heavy car with 20-degree side angle impact at midlength, and heavy car offset from unit nose at 10-15 degree impact angle) and for wrong way side angle impacts. Persons driving at speeds up to about 50 mph reported no discomfort from restraining belts in both head-on and side angle impacts. Test results proved that the G-R-E-A-T system satisfies requirements established for serviceable impact attenuators.

PROPERTIES OF GUARDRAIL POSTS FOR VARIOUS SOIL TYPES

Pendulum tests were carried out on two typical guard rail posts installed in five different soil types to determine post property variations as a function of soil conditions. Instrumentation consisted of a voice track, impact switch, speed trap, and two accelerometer channels recorded on magnetic tape. High-speed photography was attempted as a backup program for data reduction. Test results were used for post input properties in the BARRIER VII computer program to estimate the ultimate effect of soil conditions on guard rail performance. Satisfactory full-scale vehicle guard rail or median barrier tests on installations of less than 45.7 meters (150 feet) were usually achieved with exceptionally good post and soil conditions. Computer simulations with post properties indicated that barrier failure problems can be expected for severe impacts on short installations with poorer soil types. It is recommended that guard rail lengths be at least 45.7 meters unless precautions, such as concrete footings or greater post embedment depth, are taken to assure post integrity, particularly if available space behind the barrier is limited. For vehicle containment and redirection with barrier lengths of 45.7 meters or greater, end posts should be sufficiently anchored to develop full post strength in the lateral direction, along with the usual longitudinal anchorages.

DEVELOPMENT AND TESTING OF A BREAKAWAY SUPPORT COUPLING FOR LIGHT POLES (ABRIDGMENT)

Technology involved in a longitudinally-grooved breakaway support coupling system for use on light poles is discussed, and results of fatigue, vehicle crash, and pendulum impact testing are presented. The Pole-Safe breakaway support coupling is a frangible coupling designed to ensure that light poles will break away under impact. The coupling, made from die-cast aluminum, provides a breakaway spacer between a light pole and its foundation. By using this type of coupling, problems in tension and bending loads are eliminated; longitudinal notches provide high stress concentration for rapid fracture at relatively low impact levels; the ratio of service load capacity to failure load is high; and there is good control of fracture mode to insure repeat impact performance for any design impact load. Test results indicate that Pole-Safe couplings meet criteria established by the American Assoc. of State Hwy. and Transportation Officials and the Federal government for breakaway light pole support systems. Since light poles and mast arms were not damaged in vehicle and pendulum crash tests, it appears that most poles installed with these couplings will be reusable after impact. Anchor bolts in vehicle and pendulum crash tests were neither bent nor damaged when used with the couplings, and it is expected that highway use experience will be similar.

DYNAMIC TESTING OF MALLEABLE ALUMINUM TRANSFORMER BASES FOR HIGHWAY LUMINAIRES

A test program was undertaken to modify malleable aluminum transformer bases for highway luminaires with minimal equipment and labor expenditures. The program was evaluated by determining whether modifications resulted in acceptable breakaway performance as indicated by the momentum change of the impacting vehicle; and by determining whether modifications resulted in serious degradation of expected service life as indicated by a limited accelerated fatigue study. Performance appraisal of transformer bases was based on structural adequacy, impact severity, and vehicle trajectory hazard factors. Dynamic tests employed a 1,020-kg (2,250-lb) car impacting at 9 and 18 meters per second (20 and 40 mph). Fatigue tests consisted of vibrating a horizontally-mounted base and pole shaft at the resonant frequency of the pole until failure occurred. Tests indicated that a base saw cut, made horizontally to leave 76.2 by 4.76 mm thick metal on each side, would induce approximately 362 kg/second (800 lbs/second) momentum transfer and 6 g 50 millisecond maximum average deceleration in the test vehicle. Terminating the saw cut in 38-mm-diameter holes proved sufficient to induce fatigue failure in the unmodified pole instead of the base. Pole Kinematics after impact could not be determined in this program, but vehicle trajectory hazard is thought to be negligible.

PENDULUM TESTS OF BREAKAWAY WOOD SIGN SUPPORTS USING CRUSHABLE BUMPERS

Ten pendulum impact tests of breakaway wood sign supports were conducted to evaluate safety performance. Timber test specimens and signing hardware were supplied by the Michigan Dept. of State Highways and Transportation. Timber support specimens (yellow pine with pentachlorophenol preservative) were inserted into an 18-inch-round concrete footing that had been constructed with a sheet metal sleeve. Wood shims were used to insure that each specimen tightly fitted into the sleeve. Soil constituted a relatively stiff support for the concrete footing. A 1,020-kg (2,250-lb) reinforced concrete mass with a swing radius of 7.9 meters (26 feet) impacted each specimen 0.5 meter (20 inches) above grade. The front of the mass was fitted with a crushable aluminum honeycomb nose to simulate vehicle crush or deformation. In addition to the 1,020-kg impact condition, a speed of 32 km/hr (20 mph) was tested. Findings demonstrated that breakaway wood sign supports can be modified by drilled holes to effect structures which safely break away with a pendulum mass momentum change of less than 750 lbs/second. The crushable nose design has an important effect on breakaway performance, providing variations in momentum change and fracture energy related to nose design. Sequential photographs illustrate that the fracture mechanism of modified timber supports is similar across all tests.

BREAKAWAY SIGN TESTING, PHASE I (ABRIDGMENT)

Testing was conducted on New Jersey's breakaway system for large ground-mounted sign supports, to evaluate the reaction of existing structures to impact and to identify areas for further improvement. The New Jersey breakaway system consists of three basic parts other than the sign panel and posts. The base of each post is connected to anchor bolts with metal couplings and washers that break under vehicle impact but resist wind loads applied to the sign panel. The sign panel sits over a pin on the top of the post, with the lower edge of the panel held to the post by a clamp. On impact, the lower clamp breaks, permitting the post and attached pin to drop free of the panel and to rotate upward away from the panel, although still attached to the panel by a wire rope and aluminum tube (shock absorber) that extrudes and reduces force applied to the panel during restraint of the free post. A system using a heavy truck and a steel cable was devised for testing, although differences in test conditions such as lack of vehicle crush and the resulting longer impact duration precluded measuring momentum change in a definable manner. To record data in the investigation of field impacts, photographs were taken by normal-speed still and high-speed movie cameras. Consistent problems with release of the post from the signal sign panel and with the shock absorbing system were observed. A breakaway sign structure with a 6x12-foot extruded sign panel was identified as the critical size for tests, and modifications were made. The modifications are detailed. It is recommended that full-scale crash testing be conducted in accordance with Recommended Procedures for Vehicular

Crash Testing of highway Appurtenances and that the modified breakaway sign structure be installed in locations where it will be subjected to high winds.

EVALUATION OF BOLTED-BASE STEEL CHANNEL SIGNPOST

The Eze-Erect system was developed by the Franklin Steel Co. to simplify the installation of U-posts. A stub post about three feet in length is initially driven into the ground. The sign post with sign panel for single-post installation is attached to the stub post with the Eze-Erect bolted connection. A retainer-spacer strap is used in the connection, primarily to provide a close fit at the post-to-stub connection during normal loading conditions. Results of static load tests and full-scale vehicle crash tests showed that the bolted stub-sign post connection provides a simple but effective device for installing a steel U-post sign support system. Use of this connection reduces the hazard associated with driving full-length posts. Special equipment such as a lift truck or other devices to obtain required heights for driving is not required since the stub can be driven from ground level. Another desirable system feature is that the sign panel can be mounted to the sign post prior to post erection. Static test load tests show that the Eze-Erect assembly does not compromise the elastic strength of an installation. Full-scale vehicle crash tests indicate that vehicle damage is minor.

FORECASTING AUTO OWNERSHIP AND MODE CHOICE FOR U.S. METROPOLITAN AREAS. VOL. 1. FINAL REPORT

A multivariate model of auto ownership and mode choice is described, with its use in forecasting 1990 travel behavior, for a sample of 346,000 households and 407,000 workers in the largest 125 metropolitan areas. Household auto ownership decisions depend on family type and composition, household income, residential and workplace location, highway and transit service levels, and measures of overall urban spatial structure for each area. Given the number of cars owned and the variables used to explain auto ownership, each worker in the household selects one of five worktrip modes. This research advances the field of travel demand forecasting by considering auto ownership and mode choice behavior in a large number of metropolitan areas; by quantifying how metropolitan land use patterns affect auto ownership and use; by documenting the influence of racial discrimination on black household behavior; and by analyzing walk to work trips. The 1990 projections indicate that increases in household income will have the most significant impact on urban travel behavior, with changes in household composition and size and land use patterns having smaller effects.

FORECASTING AUTO OWNERSHIP AND MODE CHOICE FOR U.S. METROPOLITAN AREAS. VOL. 2, MODEL EQUATIONS. FINAL REPORT

The auto ownership and mode choice models described in Vol. 1 of this report predict the probabilities that a household will own zero, one, or two or more cars, and that employed household members will commute to work as auto drivers, auto passengers, bus passengers, rail passengers, or by walking. This volume presents the coefficients of the multivariate equations that were estimated from samples of 346,893 households and 407,731 employed household members in the 125 largest U.S. metropolitan areas. Together, the equations provide a recursive characterization of household auto ownership and mode choice decisions.

DRIVER EDUCATION AND THE LICENSING OF 16 AND 17 YEAR OLDS

Regresssion analyses were used to estimate the strength of the relationship between driver education enrollment, laws requiring driver education for licensing before age 18, and the rate of licensing of 16 and 17 year olds. A cross-sectional longitudinal data set was developed which included all data reported for several variables by any of the states and D.C. from 1965 through 1975. Results showed that driver education is significantly and positively related to the licensing rate of 16 and 17 years olds; that this relationship was much weaker than that reported in previous research; that the relationship was not greatly diminished when economic and mobility factors were controlled; and that the relationship was considerably stronger between 1971 and 1975 than between 1965 and 1970. The presence of driver education laws had a significant negative relationship with the licensing of young drivers but a significant positive relationship with driver education enrollment. These results suggest that driver education probably accounts for some increase in the licensing of young drivers. Research has indicated that the safety benefits of driver education are much smaller than generally claimed. Uncertainty about the magnitude of the effect of driver education on licensure and its safety effect in reducing crash involvement per licensed driver prevent an estimate of its net effect on total crash involvement.

FUNDAMENTAL ASPECTS OF RUBBER ADHESION TO BRASS-PLATED STEEL TIRE CORDS

A critical review of the literature on rubber-metal bonding, including adhesion to brass, primarily cover the 1970-1978 period. Extensive use of brass coatings on steel cords in steel-belted radial tires during the 1960's and 1970's has led to renewed interest in properties of rubber-brass bonding. Emphasis in the literature review is placed on rubber adhesion to brass, bond durability and degradation, the effect of compound parameters on bond strength and durability, and rubber adhesion to zinc. The rubber-brass bond is interpreted as an adhesion of sulfur cross-links to a sulfidized brass surface. These cross-links are bonded to the surface not by fully developed chemical bonds but by covalent bonds comparable to those formed by copper oxide and copper sulfide and various other organic-complexing molecules containing electron-donating nitrogen or sulfur atoms. Adhesion between rubber and brass exceeds the rubber tear strength, since there is intimate contact between rubber and sulfide film that actually grows into the polymer, resulting in a significantly enlarged contact area. There is evidence that only certain types of cross-links, probably those of the polysulfides, cause high bond strength. Brass is inherently sensitive to dezincification and other forms of corrosion. The performance of standard brass coatings in use can be optimized by lowering the plating weight or the bulk copper content, but not both. Improved corrosion resistance can be imparted to the tire cord through the lubricant system by adding substances that specifically suppress dezincification of brass by moisture. Characteristics of rubber-zinc adhesion resemble those of brass in several respects. It is suggested that zinc sulfidization should be stimulated to improve bond strength and that compounds for zinc adhesion should contain certain activators in order to level out variations in zinc surface structures that might cause partial or complete passivation of the surface.

BRINGING UP THE REAR: A BULLETPROOF 9-INCH FORD REAREND FOR PERFORMANCE CARS

Rear differentials for high-performance engines are considered, particularly the 9-inch Ford type which eliminates deflection as the pinion is forced from the ring gear under load. A major advantage of the Ford engine is its Hotchkiss-type construction. The center section is completely removable, allowing maintenance and gear changes to be done on a workbench instead of under the car. A unique feature of the Ford design is its rear pinion support bearing. Other rearends support the pinion gear only on the shank, but the Ford gear's bearing surface behind the pinion permits the gear to be supported from both sides. Numerous gear ratios are available. Theoretically, the Ford rearend has the greatest percentage of horsepower loss among performance rearends, but few find this excess drag to be a disadvantage. Various housings and center sections are available, and setting up any type of rearend is relatively easy. Tips are provided for identifying a nodular iron case, which is the most satisfactory. Use of the 9-inch rearend in car racing is discussed.

LAND MOBILE COMMUNICATIONS AND POSITION FIXING USING SATELLITES

Experiments by the General Electric Corporate Res. and Devel. Center demonstrated effective satellite-aided land mobile communications, analog and digital data relay, and automatic real-time vehicle position fixing. A station wagon was equipped with a specially designed antenna, a slightly modified commercial VHF transceiver, and a digital tone-code ranging responder that operated within the communications bandwidth. The G.E. Radio-Optical Observatory near Schenectady, N.Y., was the major earth terminal. A commercial VHF base station with a satellite antenna represented a headquaters or sector office ground station. Communications were relayed by NASA's ATS-3 geosynchronous satellite. Both ATS-1 and ATS-3 were used for position fixing the vehicle. Voice, slow scan television, audio test tones, prerecorded intrusion sensor data, and telephone patches were relayed by the satellite to and from the vehicle under a variety of conditions, demonstrating continent-wide communication of a quality comparable to fringe area reception of present local VHF mobile communications but with a notable lack of multipath flutter. Due to the high angle of signalling path, solid structures degraded communications only occasionally. Noisy radio environments degraded received signals but not transmission. Accuracy to within several hundred feet was achieved after post experiment recalibration and analysis. After similar equipment plus biomedical sensors and a medical telemetry unit were installed in an ambulance, NASA's ATS-3 satellite relayed two-way voice communications between a hospital and the ambulance and electrocardiograms from the ambulance to the hospital. Signals were received with excellent quality well beyond the range of conventional line-of-sight communications. The future of operational systems depends on the need to define user requirements, international frequency allocations, and a commitment to support the initial hardware investment. A multibeam spaceborne antenna with low sidelobes will have to be developed. A large space structure may be too expensive as a business venture, but the cost of a satellite system to serve large, thinly populated areas may possibly be less than a network of terrestrial repeaters serving the same area.

MORE MILES FROM A BARREL OF CRUDE: A FRESH WAY OF LOOKING AT AUTOMOBILE FUEL ECONOMY SPURS BACK-TO-BASICS COMBUSTION RESEARCH

Characteristics of Texaco's controlled combustion engine (CCE) and Oppenheim's plasma jet injection are examined. The CCE is not critical with respect to octane or cetane rating and has the nonthrottle advantages of a diesel. Only air is brought in on the intake stroke, and induction path and intake valve are carefully shaped to swirl air in a rotary pattern above the piston. An injector, much like a diesel injector, is positioned upstream in air swirl from the spark plug and fuel is injected as the spark occurs. As injection proceeds, fuel is swept into a localized ignition and combustion area near the plug. There is a static rather than a moving flame front and products downstream from the burning area are burned gases which cannot detonate like unburned gases in conventional gasoline engines. Professor A. K. Oppenheim, investigating alternatives to the conventional spark plug, has installed a plasma jet ignition plug. A high-voltage discharge back in the hollow nose of the plug creates radicals (ions). This ion plasma, comprised of hot excited particles, blasts from the nozzle as a high-speed plume. Since the plume is not a flame, it does not ignite like a blast from a torch. It penetrates the fuel-air mixture and sets off ignition at many random spots throughout the combustion chamber. Detonation is eliminated with multiple ignition points instead of a sharply defined flame front, making it possible to burn low-octane fuel. Although the approaches of Texaco and Oppenheim are radically different, both accomplish the same results: full breathing without a throttle; power control by metering only fuel; positive ignition without relying on fuel mix or auto ignition properties; and elimination of a detonation-engendering flame front. Both techniques are designed to achieve fuel economy. Separate sections illustrate octane and cetane measurements of gasoline and diesel ignition characteristics, and explain why diesel engines are not a long range solution to the petroleum shortage.

SURFACE TRANSPORT REGULATION AND RAILROAD PLANNING

This compilation of papers focuses on railroad planning and surface freight regulation. Topics on railroad planning include procedures for developing State rail plans, the branch line policy established by the Railroad Revitalization and Regulatory Reform Act of 1976, railroad operating costs, and strategic planning studies within the British rail system. Subjects in the category of surface freight regulation concern freight transportation and the regulation of intermodal competition; vehicle size and weight regulations, permit operation, and future trends; the performance of public agencies in safety and environmental regulation; internal cross-subsidizations in the general freight sector of the motor carrier industry; and proposals to relax motor carrier regulatory entry controls.

VEHICLE SIZE AND WEIGHT REGULATIONS, PERMIT OPERATION, AND FUTURE TRENDS

Limits on truck size and weight, practices in permit issuance, and trends in vehicle size and weight are reviewed. Commercial vehicle size and weight limits are fixed, controlled by Federal, state, and local regulations, including provisions of the Federal-Aid Highway Act of 1974. However, oversized-overweight vehicle permits are available by special application in all states, usually through state transportation agencies. Legal weight limits range from from 18,000 to 24,000 lbs for a single axle and from 32,000 to 44,000 lbs for a tandem axle. For gross vehicle weight calculation, most states rely on the bridge formula or on a table of weights using a combination of factors included in the bridge formula calculation. In approximately 87% of the states, maximum height is 13.5 feet; maximum width in 80% of the states is 96 inches. It is estimated that at least 3 million oversize-overweight permits were issued in 1975. A major problem in regulating commercial vehicle size and weight is lack of uniformity among states. Because increased vehicle size and weight yield efficiency in the form of reduced operating costs and decreased fuel consumption per unit of payload, the trend toward increased vehicle size and weight is expected to continue. The impact of larger vehicles must be evaluated in relation to safety considerations.

TEMPERATURE CALCULATION AND PRACTICAL APPLICATION OF BRAKE DISKS (TEMPERATURBERECHNUNGEN VON BREMSSCHEIBEN UND IHRE PRAKTISCHE ANWENDUNG)

The adverse effect of a bad choice of pad combinations on braking stability and traffic safety is explained, using a friction-coefficient-scatter diagram. Vehicle adjustment can be considerably affected by change in friction coefficients of brake linings on rear and front axles. Manufacture-related scatterings of friction coeficients are partially responsible for this, along with friction coefficients that can occur during vehicle operation. A case in point is the increase in brake disk temperature during prolonged downhill driving or frequent braking at high speed. Using temperature variation at front and rear axles as a function of time, it is shown how vehicle brake adjustment changes as a function of temperature with prescribed changes in friction coefficient. Basic temperature calculations for vehicle brakes are given for heating in the braking phase and cooling. Various driving cycles are described (normal load for a brake system, downhill travel as an extreme load, and a collective load for a city bus). The dependence of brake lining friction coefficients on fabrication scatterings and friction surface temperatures is discussed, and the impact of brake lining temperature behavior on the locking sequence is examined.

AN EMISSION TEST FACILITY FOR MEASURING CATALYTIC CONVERTER EFFICIENCIES

Sixteen gas analyzers were used to measure emissions into and out of the catalytic converters while conducting Environmental Protection Agency vehicle test procedures. A computer system controlled the analyzer consoles, logged test data, and provided test results quickly. The data logged by the computer during testing was transmitted on command to the GM Res. Labs (GMR) Data Center, where data reduction was done, because it has a large computer to do the calculations, and programmers to maintain the reduction programs. The test summary can be transmitted back to the test site. The system was tested extensively to verify accuracy of results. Gas analyzers were calibrated, data logging and handling were checked, and the data reduction programs were scrutinized. The major programs involved are calibration, predata entry, range table edit, scheduled testing, post test data entry, data file edit, data transmission to data center, and summary receive and print. The system has given consistent results during its operation.

COMPUTERIZED FACILITY FOR ENGINE DEVELOPMENT

Design improvements made on a 20-year-old engine testing facility are discussed. Significant improvement was obtained with computer controlled data acquisition and permanent storage; computer generated volt/time test tables for automatic speed and torque durability testing; a data processing facility for formatted hard copy and plots; a new dynamometer system including wound armature d.c. dynamometer, solid state control for improved speed and torque control, road load, windage, and inertia simulation, and circuit module to directly interface computer to dynamometer controls. Other improvements featured a palletized engine to minimize installation time to dynamometer; a stand-alone Data Acquisition and Control Console installed to improve operator control and safety; alarm display system to minimize trouble shooting down time; modular concept for instrumentation trouble shooting and repair; a speed modulated spark angle measurement system; a dynamic fuel measurement circuit; a multi-range air rate measurement system; and utilization of wire routing, control isolation and grounding techniques. The changes provide development personnel with improved data accuracy and formatted test results in much less time. Data output, based on the number of tests performed, has doubled. Flexibility of basic controls, instrumentation, and computer applications has facilitated compliance with requests for special instrumentation and/or data, although software programming work load has increased. Similarity of the test cells has several advantages: permitting flexibility in their assignment to development projects, and facilitating trouble shooting, repair and preventive maintenance, as well as the on-going updating of the cells by allowing one design of an improvement to be applied to all cells.

HOW TO BUY A TRUCK FRAME FOR A UTILITY VEHICLE

Engineering considerations are discussed which are involved in the proper selection of a medium or heavy duty truck frame for utility vehicles, with primary emphasis on the mounting of aerial devices, including digger derricks, hoists, cranes and man lifts. The truck chassis and utility body with aerial device must be compatible and assembled by expert personnel; the aerial device must be of proper size and capacity to handle the loads with an adequate safety margin. Choice of mounting location and method is dictated by the function of the aerial device and by load capacity, cargo space and body requirements. The chassis must have the necessary frame and suspension characteristics to mount and support the device with utility body under all dynamic and static operating conditions. The following chassis terms are explained: "moment of inertia", "section modulus", "yield strength", "bending moment", "resistance bending moment", "torsional resistance", and "stability", all of which affect a structure's ability to carry load and resist deflection. The qualities of front and rear axles, springs and brakes are also discussed. Considerations necessary in locating the aerial device on the chassis include: use of a subframe, back-of-the-cab location of the pedestal, need for full length contact between the mounting plate and truck siderails, and method of attachment.

HOW TO BUY A BODY FOR A UTILITY TRUCK

In developing specifications for a body of a utility maintenance and construction vehicle, all its possible uses must be considered. Choices for gas, telephone and electrical power company vehicles are made among the light-duty service vehicles, with chassis of less then one ton capacity, or the heavy-duty maintenance vehicles for city, rural, or special use. Items to be considered include the chassis (clearance, accessibility, center of gravity); the load requirement; auxiliary equipment, both driven from the main engine and self-powered; safety equipment; security; personnel accommodation; weather protection; sound deadening qualities; color and paint; and cost recovery. For special use vehicles, fiberglass or aluminum is preferable to steel because of rust. The three basic types of utility body construction are the welded steel body (average life of ten years); the second in popularity, an aluminum body on a steel frame, made by aircraft-type riveting and aluminum welding (body life of up to 20 years); and the more recent fiber-glass body on a steel frame (life expectancy of at least 20 years). This type is highly resistant to rust, but the cost is considerably higher.

DIESEL ENGINE WEAR WITH SPIN-ON BY-PASS LUBE OIL FILTERS

Engine tests were conducted to determine the effects of various full flow and by-pass lubricating oil filter combinations on diesel engine wear. The filter performance was determined by measuring the wear of piston rings, main, and rod bearings in a Cummins NTC-335 engine, after contaminating the lube system with a known amount of AC Fine Dust to accelerate wear. Comprehensive tests of over 200 different types of filter media showed that only the stacked disc spin-on by-pass filter and the conventional 750 depth-type filter reduced engine wear effectively by controlling the small abrasive particles in the oil. These two filters were equally effective in reducing engine wear. The pleated paper spin-on by-pass filter passed bench test requirements, but was ineffective in actual engine wear tests. A reduction in engine oil capacity of 7.57 liters (2 gallons) did not substantially affect engine wear, but reduced oil capacity may affect maintenance intervals. Engine wear was directly related to the degree of filtration of the by-pass and full flow filters and the levels of abrasives left in the oil. The use of the combination full flow and by-pass filter system can reduce the wear rate to less than 1/2 that resulting from use of a full flow only filter system. Due to extended engine life with use of an effective by-pass filter, the extra cost of installing and maintaining the by-pass filter is recovered many times over, providing the lowest total cost for the engine user.

AUTOMOTIVE LUBE OIL FILTERS FOR EXTENDED SERVICE AT HIGH CRANKCASE OIL TEMPERATURES

Passenger car engine lubricating oil filter advancements have been made to improve filter reliability. The design consists of a dual media laminate for greater dirt holding capacity and improved resistance to higher crankcase oil temperatures. Laboratory bench testing shows significant advances in dirt holding capacity for dual vs. single media filters; data on tests are provided. Filter testing, with a fleet of 15 delivery vans, showed service life to be at least 15,000 miles with potential for longer service. Evaluation is continuing on engine-related results, and development is proceeding on a "new generation" filter intended to possess even greater heat resistance performance, utilizing the dual media concept with synthetic fiberfill in the primary media itself. Improvements are also being made to the sealing gasket compound to insure seal integrity under severe heat conditions.

MOTOR GASOLINES, WINTER 1978-79

Various refiners, motor manufacturers, and chemical companies collected 2,358 samples of motor fuels from service stations throughout the country. The samples were analyzed and the data submitted to the Bartlesville Energy Technology Center (BETC) for study, necessary calculations, and compilation, under a cooperative agreement between the BETC and the American Petroleum Institute. The samples represent the products of 52 companies, large and small, which manufacture and supply gasoline. These data are tabulated by groups according to brands (unlabeled) and grades for 17 marketing areas and districts into which the country is divided. A map shows marketing areas, districts, and sampling locations, and charts indicate the trends of selected properties of motor fuels since 1946. Twelve octane distribution percent charts for areas 1, 2, 3, and 4 for unleaded, regular, and premium grades of gasoline are presented. The antiknock (octane) index (RM)/2, averages of gasolines sold in this country were 88.7, 89.6, and 94.2 unleaded, regular, and premium grades of gasolines, respectively. Significance of the data presented is not discussed.

LAWS FOR LAWS' SAKE? [VEHICLE RECALLS]

Safety-related car recalls in the United States are considered in relation to similar proposed legislation in Great Britain. Even though government requires the motor industry to spend large sums of money on developing safer, cleaner, and more fuel-efficint vehicles and juries award significant damages against manufacturers in product liability cases, measures to assure that car owners keep their vehicles in good repair are sketchy. It is estimated that $20 billion of $50 billion spent on car repairs annually involve unnecessary or fraudulent work. The Center of Auto Safety, established by Ralph Nader in 1979, indicates that car problems represent the largest source of consumer complaints. The U.S. accident rate is 3.3 deaths per 100 million miles, compared with 4 deaths in Great Britain and Norway, 7.9 in West Germany, 8 in France, 22.5 in Portugal, and 32.2 in Turkey. In 1978, 13.5 million cars were recalled for the correction of defects; 14.5 million tires produced by Firestone were recalled. Ford had the most recalls, with 37 recall campaigns involving 3.6 million vehicles. Ford's biggest problem was the recall of 1.4 million Pintos and Mercury Bobcats because of "rolling bomb" rear collision fires and consequent deaths. Transmission slippages were also a problem. Cited examples demonstrate the range of safety-related recalls in the United States and the requirement that manufacturers guarantee emission control equipment for 50,000 miles or five years. Also mentioned are "secret warranties" and fraudulent warranty practices.

MOTOR COPS

Dangers related to the work of motorcycle police officers are considered. Motorcycle cops are generally used by law enforcement agencies because motorcycles are more maneuverable than cars and the combination of maneuverability and power-to-weight ratio makes motorcycles ideal pursuit vehicles. A disadvantage of motorcycles is the high cost of operation. Since motorcycles are personal machines by nature, suited to only one rider, they cannot be shared by two or more shifts like patrol cars. The man-hour cost of operating motorcycles is significant, including the increased accident risk to motorcycle police officers since they operate mainly during peak traffic hours. The evolution of police motorcycles from Harley Davidson to newer Japanese models is described. Although various types of motorcycles have been developed to minimize hazards and mechanical failure, road conditions still have to be taken into account. Weather changes can seriously affect road conditions. Foggy weather is more dangerous than rainy weather in terms of visibility. Ways to maintain safety during motorcycle operation are noted, and a training course for motorcycle police officers is briefly described.

ACCIDENTS INVOLVING HANDICAPPED DRIVERS

The development of adaptive aids to enable handicapped people to operate a motor vehicle is reviewed, including a summary of the literature on driving by the handicapped. Standards developed by the Veterans Administration (VA) for such aids affect only a small group of the handicapped driving population. Previous studies comparing accident involvement of physically impaired with nonimpaired drivers suggest that the assertion that handicapped drivers are especially safe is based on weak and conflicting evidence. The relative accident involvement of handicapped drivers, restricted to use of full hand controls, was compared to that of other drivers. A driver population file of 8,698,536 New York State drivers was examined, including various groups of the handicapped, notably 3,336 drivers restricted to use of full hand controls. The control group was limited to 120,934 drivers, randomly selected. The data show that handicapped drivers using full hand controls had a statistically significant higher accident rate (per driver) than other drivers, and that their accidents differed significantly from those of other drivers by several accident variables such as weather conditions, road system, and accident type. The relative driving exposure of each group should be taken into account, as well as driver experience and the reliability and state of wear of the special mechanical equipment. It is concluded that although handicapped persons are not necessarily poorer drivers, they need adequate equipment, training, and driving experience to meet or exceed the safety records of other drivers. Additional studies are recommended.

DRUNKEN DRIVING IN FINLAND. LATE-NIGHT, WEEKEND INCIDENCE IN FIVE COMMUNITIES IN 1978

A study was conducted to reveal the relationship between driving while intoxicated incidence and knowledge of the new law concerning drinking and driving, in southern Finland. Twelve roadside surveys with a total of 43 single controls were conducted in five communities, on Friday and Saturday nights during spring and summer 1978. All passing motor vehicles were controlled by the police, 2074 drivers were given breath tests with the Alcolmeter, and a random sample of 500 drivers was interviewed. A positive alcohol result was obtained for 1.7% of all drivers. In six cases (0.3%) the blood alcohol result was between 0.50 and 1.50 per mille and in five cases (0.2%) it exceeded 1.50 per mille. These results suggest that the incidence of drunken driving during spring and summer weekends seems to be quite low in the examined areas. Driver interviews revealed that on an average, 41% knew exactly the statutory blood alcohol limits, and 56% had no idea of the penalties for drunken driving. Of all interviewed drivers, 7% were abstainers, with no reason to be aware of the drunken driving law.

A BRIGHT FUTURE FOR WHEEL BALANCING

Safety and performance factors in automobile tire manufacture and use are discussed, particularly for radial tires. The most common factor affecting the performance of belted, high-mileage radial tires is uneven tolerance or nonuniformity in the match between tire and wheel. A tire, being elastic in nature, conforms to the shape of the wheel. Thus the tire will not be round if the wheel is not perfectly round, causing problems in vehicle ride. Various densities of rubber in a molded tire cause different flexing characteristics of radial sidewalls to occur, a condition labeled radial force variation. Test results by General Motors, Uniroyal, General, and other tire manufacturers show that the field service concept where tire and wheel are adjusted (matched) to compensate for radial force variation can eliminate most vehicle vibration. Tire matching is a two-step process that involves the coordinated use of two machines, the Tire Matcher system developed by Autodynamics/Ride Control and an advanced, solid-state two-plane wheel balancer. Electronic wheel balancers are designed to deal with static, dynamic, and couple imbalance by electronically splitting a tire in half and evaluating each half independently. Tire matching detects uneven tolerance in a tire-wheel assembly under simulated driving conditions and removes these variations to assure a smoother ride. Important changes affecting ride quality in cars of the future concern car weight, small-diameter wheels, and an increase in air pressure to lower a tire's rolling resistance. Costs associated with tire matching are examined, as well as the significance of increased tire matching business to the tire service industry.

IT'S TIME TO "CRY HAVOC"

The causes of the present heavy highway fatality rate are reviewed, with the preventive measures that could improve the situation. Stress is laid on the responsibility of the individual to family and friends in preventing anyone from driving who has had too much to drink. The use of motorcycle helmets is urged. Since 1976, when Congress revoked the Federal authority to impose sanctions against states without a mandatory helmet law, 26 states have either repealed or weakened their helmet use laws. Motorcycle deaths increased by 24% in 1977, to an all-time high of more than 4100, and increased another 5% in 1978. Studies show that helmet usage in states with mandatory laws is about 94%, but drops to 60% or lower in states without such laws. Seat belt usage in the U.S. is very low (about 14%) and there is no public support for mandatory seat belt laws. Starting in model year 1982, automatic restraint systems such as air bags or automatic belts will be required in the front seats of all full-sized cars; by model year 1984, all passenger cars will be required to have automatic restraint systems, type unspecified, but above a certain level of protection. It is estimated that 9,000 lives may be saved each year by this requirement. A successful effort has been made to produce prototype Research Safety Vehicles demonstrating the possibility of designing smaller cars that are at once safe, fuel efficient, low polluting, practical and economical. Some aspects of this research have been put into some production cars, but the superior performance of the prototype research vehicles is not yet matched by any manufacturer.

PHYSICIAN REPORTING OF THE IMPAIRED DRIVER

Legislation is recommended to require physicians to report driver disabling medical conditions. The principle of confidentiality of medical information is not abridged when it is necessary to protect the individual or the community. Alcohol impairment, neurological and mental disorders and medically restrictive conditions such as diabetes and cardiac disease, as well as fatigue, stress, and minor but temporarily endangering diseases which diminish driver attention comprise the largest groups of conditions that affect driving. The early work of Dr. Fletcher Woodward in advocating the modern multidisciplinary approach to traffic medicine is cited. Rights of highway users, workers and children to be protected from impaired drivers are discussed. Physicians are urged to acquaint legislators with the need for legislation permitting reporting of conditions medically endangering to the public and the individual, while providing legal immunity for the reporting physician.

12-VOLT AUTOMOBILE VACUUM CLEANERS

Advantages and disadvantages of automobile vacuum cleaners are explored. Of products from three manufacturing firms, testing by Consumers' Research Magazine indicated that all vacuum cleaners had a fair ability to remove soil embedded in the nap of rugs, but because of the limited suction, only small stones (less than 1/8 in) could be picked up. Most vacuum cleaners removed sand that had been sprinkled on the rug surface and they were almost as effective as a regular canister in the removal of dust and fine debris on smooth surfaces. Crevice tools were effective in getting into narrow spaces next to the center console in cars equipped with bucket seats. In most of the 12-volt vacuum cleaner models tested, suction is produced by a motor-driven impeller revolving at high speed that draws dirt into the nozzle and removes it from the air stream by a single-cloth filter. Filtered air then flows past the impeller and is discharged under pressure back into the car. Design factors to consider in the selection of an appropriate vacuum cleaner type are identified. Information on automobile vacuum cleaner ratings is presented.

ALCOHOL AVAILABILITY, CONSUMPTION AND THE INCIDENCE OF ALCOHOL-RELATED SOCIAL AND HEALTH PROBLEMS IN MICHIGAN. FINAL REPORT

Cross-correlation, time-series-modelling and multiple regressio analyses were utilized with available data from sources i Michigan to explore causal relationships between beverage alcohol licensing actions of the Michigan Liquor Control Commission, alcohol beverage distribution, and a number of majo social and health problems. While conclusions are not definitiv because of limitations in the data, it was found that mortalit due to traffic accidents, occupational accidents, and total reported accidents is strongly and consistently associated with increases in alcohol availability and with draught and package beer distribution. Other analyses using time-series analysis techniques determined that beverage alcohol distribution is highl predictable. Multiple regression analyses, interpreted in connection with the other findings, suggested that wine distribution probably more vulnerable to changes in licensing activities tha beer or liquor distribution. Implications of the findings an suggestions regarding data collection adequacy in Michigan ar offered. Appended are time-series plots of selected Michiga alcohol consumption and distribution of licensing variables wit selected Michigan health and social problem frequencies, and graph of the estimated population of Michigan, 1970-76.

MOTORCYCLE SAFETY EDUCATION AND LICENSING

Existing motorcycle driver licensing and driver education laws were reviewed, as well as regulations relating to motorcycle driver licensing and motorcycle safety education, and model legislation incorporating the best of current practices was prepared. Two resulting model programs are outlined: the Model Motorcycle Driver Licensing Program and the Model Traffic Safety Education Program. Both contain statutory guidelines to be incorporated into the state's statutes, and implementation guidelines suggesting the substance of necessary or desirable administrative regulations to implement the statutes. An analysis of the existing laws and regulations of the states is also presented.

AMBIENT TEMPERATURE, FUEL ECONOMY, EMISSIONS, AND TRIP LENGTH. FINAL REPORT

The relationship is examined among automotive fuel economy, ambient temperature, cold-start trip length, and drive-train component temperatures of four 1977 vehicles, one each from the sub-compact, compact, intermediate, and full-size classifications. Fuel economy, exhaust emission, and drive-train temperatures were measured at ambient temperatures of 20 degrees F, 45 degrees F, 70 degrees F, and 100 degrees F, using the 1975 Federal Test Procedure (75 FTP) and the EPA highway fuel economy test (HWFET). Appended are vehicle description and fuel inspection data, and data on fuel consumption and emissions; fuel consumption, emissions, and trip distance; fuel consumption at 1-mile intervals of the FTP; engine and drive-train temperatures; and steady-state temperatures, torque, and fuel consumption. At 20 degrees F ambient temperature, the fuel economy for a 3.6-mile cold-start trip was only 47% of the warmed-up 70 degrees highway fuel economy; the cold-start 31.6-mile trip at 20 degrees F ambient temperatures shows fuel economy of 78% of the 70 degrees highway fuel economy. Cold-start trips at 70 degrees F show respective values of 65% and 86%. Short cold-start trips have a drastic influence on carbon monoxide and hydrocarbon emission rates, with greater effect at decreasing ambient temperature. Oxides of nitrogen were only slightly affected by the change in temperature and trip length for the conditions of the study. The effect of cold-start trip length on fuel economy was similar for the four tested vehicles, and results indicate that the driving duty cycle has a marked effect on cold-start short trip fuel economy; for estimates of fuel usage and effects of vehicle changes on fuel economy, driving patterns used to measure trip effects should cover a range of duty severity. The ambient temperature affected the rate of warm-up of the transmission fluid and differential more than it did engine oil. The data indicate that current-production autos suffer as much as somewhat older models in the ratio of cold start to warmed-up fuel economy and emissions penalty; much further improvement is possible in cold weather fuel economy and emissions.

AUTOMOTIVE MANUFACTURING ASSESSMENT SYSTEM. VOL. 1: MASTER PRODUCT SCHEDULES. FINAL REPORT

The development of the Master Product Schedules for the major U.S. automotive manufacturers resulted directly from work performed on the design of the Automotive Manufacturing Assessment System data base, a system to assist in the evaluation of industry's capability to produce fuel-efficient vehicles. Through extensive research and synthesis of publicly available information, the schedules were generated to portray chronologically, current and future product changes and technological advances for each domestic automobile (1975-1985), light truck (1975-1980), and selected import manufacturers (1975-1980). The schedules show (by make, model, and year) all new vehicle introductions, highlighting downsizing; styling changes; and significant technological advances in the areas of engines, transmission, fuel metering, emission control, and safety. Extensive notes and reference lists are tabulated. The Master Product Schedules are given for General Motors, Ford, Chrysler, American Motors, International Harvester, Toyota, Datsun, Honda, Subaru, Mazda, Volkswagen, Fiat, British Leyland, Volvo, Mercedes-Benz, and Saab.

WEIGHT STUDY: 1978 CHRYSLER OMNI. FINAL REPORT

Results are presented of a weight study on a standard 1978 4-door hatchback Chrysler Omni. All components were disassembled, weighed, photographed, analysed for material content, and the manufacturing process determined. The study was designed to develop baseline data on automobile material usage, structural design, and weights, for use in future studies relative to improvements in fuel economy for the automobiles of the

1980's. In addition to body weight and chassis weight data tables, photographs of all disassembled components are presented, as well as graphic illustrations showing construction of major Omni body and chassis components. A cost/teardown study had previously been made on a 1976 VW Rabbit; because of the similarity of the two vehicles and availability of the data, comments are also made on significant differences between the two vehicles.

DETERMINATION OF TIRE QUALITY FROM NONDESTRUCTIVE INSPECTION. FINAL REPORT

A study was performed to determine the capability of an ultrasonic inspection system developed at the Transportation Systems Center to identify anomalies in tires which would cause failure during the compliance test under Federal Motor Vehicle Safety Standard 109 and to identify degradation of tires which had passed the compliance test by subsequent examination. In a population of 1440 tires, it was found that all tires which failed the compliance test had multiple anomalies detected previously by nondestructive inspection (NDI). It was not possible, a priori, to determine which of these anomalies would lead to failure. A ranking procedure was developed which utilized the NDI results and other factors to grade and rank each tire. By statistical analysis a threshold grade was determined to separate the groups in which all tires passed the compliance test from the groups which contained tires that failed the test. The confidence level in the nonrandom nature of this threshold is near 99%. By subsequent NDI, it was found that 43 tires which had passed the test had undergone some degradation. Copies of the NDI printouts are included.

COMPARISON OF PRE AND POST ROAD TEST ULTRASONIC INSPECTION RESULTS ON 134 PASSENGER TIRES. FINAL REPORT

Data were compared from 134 tires prior to and after road tests in order to determine whether excessive tread wear could be related to characteristics detected by ultrasonic inspection. The comparative analysis revealed that nine tires had substantial changes which may be related to abnormal tread wear. Five tires developed radial runout or shape discontinuities in the sidewall; the other four had shoulder variations. Copies of the printouts from the nondestructive inspections are included.

CORRELATION BETWEEN ULTRASONIC NONDESTRUCTIVE INSPECTION AND WHEEL TEST OF 34 RETREADED TIRES. FINAL REPORT

Thirty-four retreaded tires were inspected using reflection ultrasound nondestructive inspection (NDI), wheel tested, and then subjected to failure analysis by sectioning. The results demonstrate for the first time the ability of ultrasound to identify and classify tire defects which lead to failures. The NDI identified five tires which had major flaws, predominantly (tread or belt edge) separations, and five tires with minor flaws. The wheel test was an 8-hr, full-load 55 mph test in which six of the 34 tires failed. All six failed tires were analyzed by Fabric Res. Labs., and the results were compared with flaw assessments made by NDI. All six failed tires came from the ten identified by NDI as having flaws, five of which were identified as having major flaws by both NDI and failure analysis. Copies of the NDI printouts are included. It is recommended that the National Hwy. Traffic Safety Administration use the ultrasonic inspection technique to support its ongoing rulemaking and enforcement activities, particularly in the area of identifying and defining separations as cited in Federal Motor Vehicle Safety Standard (FMVSS) 109, New Pneumatic Tires, and buff damage as cited in FMVSS 117, Retreaded Pneumatic Tires.

COLLISION AVOIDANCE RADAR BRAKING SYSTEMS INVESTIGATION--PHASE 3 STUDY. FINAL TECHNICAL REPORT

The potential application of an anticipatory radar braking system in preventing motor vehicle accidents is studied. The design of the experimental radar braking system is described, as well as the installation of the system on two test vehicles (1977 Ford Granada and 1977 Plymouth Fury). A summary of the functional tests which demonstrate the performance of the experimental system is included. The design of the radar sensor is outlined, including the signal processing electronics, control panel display, and installation of the entire subsystem on the test vehicles. The design of the brake actuation subsystem and the anti-lock subsystem are described, including installation information. Functional tests were conducted with the two test vehicles equipped with the radar braking system to demonstrate its performace. There were significant differences in performance between the two radar-equipped vehicles. Braking response differences were apparently caused by mechanical differences in the vehicles' foundation braking systems, although the response characteristics of both systems were somewhat higher than desired. Both systems braked early on dry pavement at low speeds. Braking distances at higher speeds were marginal on dry pavement due to slow brake response time. Wet pavement performance was degraded because of reduced coefficient of friction. Better braking performance was achieved with anti-lock braking in operation (shorter braking distances and maintenance of better lateral stability). More extensive tests of the radar braking system installed in the test vehicles are recommended. Because of the experimental nature of the system and potentially severe consequences of closed loop operation, it is recommended that vehicle testing be restricted to dedicated sites and conducted by qualified test drivers.

VISUAL DETECTION OF DRIVING WHILE INTOXICATED. PROJECT INTERIM REPORT: IDENTIFICATION OF VISUAL CUES AND DEVELOPMENT OF DETECTION METHODS

The initial phase is described of a two-phase project on the visual, on-the-road detection of persons driving while intoxicated (DWI), designed to develop and test procedures for enhancing on-the-road detection of DWI. The emphasis of the first phase was on the identification of visual cues and the development of procedures that effectively discriminate between DWI and driving while sober (DWS). The literature was reviewed, expert opinion was surveyed, 1288 DWI arrest reports were analyzed, and an on-the-road detection study was conducted, during which trained observers accompained police officers on patrol and recorded 643 instances of driving behavior and vehicle actions that deviated from normal. In each instance, the patrol officer stopped the vehicle and measured the blood alcohol concentration (BAC) of the driver with a portable breath tester. A DWI detection guide was developed to facilitate the application of research findings to the on-the-road detection of DWI by police patrol officers. The guide consists of 23 visual cues, with each cue given a value reflecting its ability to discriminate between DWI and DWS, and a set of three rules for estimating the probability of DWI for any set of observed cues. The 23 cues accounted for 92% of the cues observed during the detection study. It was concluded that alcohol-induced driver impairment is exhibited in the functions of steering and velocity control, time-sharing of attention, and information processing; that most detection events can be accounted for by a relatively small number of cues; that certain subsets of cues frequently occur together; that visual detection cues vary in the frequency they occur with DWI and in their discrimination ability; that conditions under which cues are observed have relatively little influence on cue occurrences; and that patrol strategy affects the relative frequencies with which cues are observed. A field test of the DWI detection guide is recommended to evaluate the guide prior to its widespread use.

EARLYRIDER LOAN A SEAT. HOW TO ESTABLISH AND OPERATE AN INFANT AND CHILD RESTRAINT LOAN PROGRAM

This manual is designed to aid service organizations and other groups in establishing an effective child restraint loan program. Reasons for a restraint loan program, administrative details, and references to groups who have operated such a program are presented. Necessary personnel and their functions, and space and supplies/equipment requirements are outlined. Acceptable types of restraints, where to obtain the first group of them, rental fees, selling restraints, and sales and use taxes are discussed. Ideas for helping others sell or swap, and attracting parents to the program are provided. The usual procedure for loaning a seat is described, and liability and evaluation of program impact are mentioned. Apended are a description of some typical programs, a shopping guide to restraints, a list of restraint manufacturers, a sample of the application for retailer's license in Michigan, sample rental form, sample return reminder letter, and addresses of governor's highway safety program offices in each state and U.S. jurisdiction, as well as other sources of child restraint informational materials (including the ten regional offices of the National Hwy. Traffic Safety Administration).

EARLYRIDER FACT BOOK [CHILD RESTRAINTS]

This booklet, which provides a detailed look at currently marketed infant and toddler automobile safety restraints, is intended as a guide for community organizers of programs to increase child restraint usage, as well as a study guide in selecting seats. It can also enable observers to recognize seats during an observation survey. Common mistakes parents make in using child restraints are outlined. Restraints are divided into three major categories: those for infants only, usually up to 17-20 lb; convertible restraints which can be adjusted to face either forward or backward; and restraints designed only for children old enough to sit up by themselves in a forward-facing position. A fourth category briefly covers recently discontinued restraints (all adequate). As of Feb 1979, this is a complete listing of infant and child restraints which passed dynamic tests according to the requirements of the 1978 proposed revision to Federal Motor Vehicle Safety Standard 213. Three newly marketed restraints are included which have not been formally tested in final production configurations, but performed adequately in preproduction tests. Each restraint model is illustrated, and manufacturer, price and availability, description, and comments provided.

EARLYRIDER PUBLICITY HANDBOOK [CHILD RESTRAINTS]

This booklet is designed to aid service organizations and other groups in developing a diverse public communications program that will effectively promote child restraint use in the community. Basic pointers for publicity are outlined, including guidelines on how to prepare information for the media (writing news relases, planning picture publicty, arranging radio and television coverage). Sample news releases are provided (start of program, incident where child properly restrainted is uninjured in a crash). Information is given on how to conduct a survey of child restraint usage in the community. A quiz is provided which can be used as the basis for an enjoyable, informative group discussion on restraint use.

EARLYRIDER EDUCATIONAL CURRICULUM. THE HEALTH PROFESSIONAL'S ROLE IS PROTECTING THE CHILD PASSENGER

The goal of these educational materials for health professionals is to provide the means by which child auto safety can become a routine part of preventive care within the health community. An outline is presented of a training session for health professionals to prepare them for carrying out child restraint education for expectant parents and parents of young children. Guidelines are presented for the instructor of the training session, as well as for the health professionals (prenatal approaches to safety education, in-hospital education for the new parent). Resource materials are indicated, and a glossary provided of terms related to child restraints. Appended are demonstration techniques for infant and child auto safety restraints, and general guidelines for health professionals in promoting child restraint usage in the community.

TRAFFIC SAFETY '78. A DIGEST OF ACTIVITIES OF THE NATIONAL HIGHWAY TRAFFIC SAFETY ADMINISTRATION

Key features are presented from the 12th annual National Hwy Traffic Safety Administration (NHTSA) reports as mandated b the Highway Safety Act of 1966 and the National Traffic an Motor Vehicle Safety Act of 1966. These acts require the Secretary of Transportation to report on progress made during th year in reducing traffic accidents, fatalities, injuries, and property damage. The magnitude of the highway safety problem i discussed, including persistent problems (e.g. nonuse of safet belts, drunk driving, noncompliance with 55 mph speed limi inadequate crash protection) and current trends (e.g. increase traffic fatalities and fatality rates, decreased helmet usage, growing number of trucks on the road, increased auto repair waste) Areas of activity in NHTSA'S overall safety program includ the 55 mph speed limit; van and light truck standards; chil restraint standard; fuel economy standards; pedestrian, bicycle and motorcycle safety; and alcohol involvement in accident The agency's activities to improve the safety and fuel econom of motor vehicles are described, including consumer informatio programs and recall campaigns. NHTSA'S involvement in an sponsorship of efforts to improve traffic safety are discusse Public education and the encouragement of consumer participation in traffic safety and motor vehicle matters, and NHTSA' international activities are mentioned.

RULES OF THE ROAD RATED [1979]

A rating is made of state traffic laws (including those of th District of Columbia, and Puerto Rico), compared with th rules of the road part of the Uniform Vehicle Code (UVC) as c 1 Jan 1978. Prior ratings were based on state traffic laws c 1968 and of 1971 through 1976. A more precise picture of th status of state traffic laws is sought that will facilitate rapi identification of particular areas of a state's laws which do nc conform to the UVC; that will indicate areas of the statutor law where uniformity may be markedly poor nationwide; an that will identify states whose traffic laws may need immediat upgrading in order to improve highway safety. Numerical a sessments of the states are provided in 13 tables, one for eac article in the "Rules of the Road" chapter of the UVC an subdivided by section, subsection, or principle in the Code. summary table provides the number of points for each table an the total points scored for each state. The highest ranked state Kansas, the lowest is Massachusetts. Between 1976 and 197 the scores in 23 states improved while the scores in seve worsened; 22 scores remained the same. Although many stat made significant advances toward uniformity during 1969-197 200 substantial differences still remain. Almost 45% of the differences involve traffic control devices and right of way. disappointment was the failure of 14 states (mostly in the easter half of the U.S.) with poor scores to make greater progres these states accounting for a large percentage of all substanti differences.
